Source record: 31775

No, I'm tasting gun metal yet but if you are experienced with the AD9850 DDS please read on.

I am clocking out 40 bits serially to the unit, data word + control, for some reason the DDS only updates the output freq based on the results of the first 16 bits. When powered up the unit is stable, not misbehaving and seems to respond with the exception of the last 16 bit freq bits. If the last 16 bits are set to 0 the output results are the same as when they are vaild. It jumps about 600 hz or so instead of 10 hz

What has be scratching my head is that it must be "seeing" the last 16 bits and control word or it wouldn't come alive. Has anyone any input on what may be missing, similar problems? I clock out 32 bit freq control, then 8 bit control word then a 10us wide F_update pulse. Again, stable, working but ignoring last 16 bits.

Using a PIC 16F73 and simultaneously dumping the 4, 8 bit words out the serial port I get:

Changing freq starting with 7.10000 by 10 hz

freq 7.10001 %00101101%01110000%10101000%00001000

This is a very interesting discussion
I have thought about doing this in the past, but have never been brave
enough!
What about a scheme like:
Input -> attenuator -> LO/mixer->LPF/if amp ->Direct coversionLO/Mixer
-> switchable LPF to say 150KHz -> Log det (broadband)-> ADC -> software
/PC

For a 100MHz sweep you would probably need 300KHz bandwidth max which
would be achieved by a 150KHz DSB receiver.
You could go higher than 100MHz as the first IF - use ring diode mixer
to a helical filter as the roofing filter
I would be interested in a cooperative project

Hi Tim,
the serial data are clocked beginning with the LSB up to MSB and the
control word ends the sequence. It is legal to issue e.g. one or two
bytes followed by the FQ_UD pulse for fine tuning. Did you try it ?
I have had a similar experience with AD9851, which IMHO uses the same
protocol. The error was in the firmware routine sending serial data
and W_CLK to the port, not in the DDS chip.

Sorry to bother the group, a typo in the source code was the problem.
The DDS VFO is now smooth as silk... See you on 40m CW

======
Having a 5 volts filament ,requiring 14.5 Amperes ,would make it a nice 70 +
Watts (anti-condensation) heater.

Applying 12V would turn it in a 'RIP state' within a few seconds.

Oh, my....*sigh*

No, I don't work for the power companies,
and no, I don't lobby for BPL.

charlesblabham wrote:

>..it encourages us all to be discouraged....
Now *that* is an interesting concept..

>
> I am sorry to hear that this invasion of non-ham stuff

I thought innovating, finding new ways around problems, etc.
was "ham stuff." We used to do that alot.

> So far, the idea of using non-ham links in order to "improve" the
> performance of amateur radio has been 100% consistent. In every case where
> it has been applied, it has managed to set back
> and denigrate the hobby, to some extent or another.

When CW replaced spark, it was going to
"make the hobby too complicated and expensive to continue."

When SSB came on the ham scene, "Donald Duck"
was going to "destroy the hobby."

When FM and repeaters came along, they were
"against the spirit of ham radio. You might as well use a telephone!"

When Packet appeared, they brayed:
"those 'brrrrappp!' signals are denigrating the hobby!"

Throughout our history, hecklers and naysayers have been full of beans.
And they're full of beans now.

In the next rewrite, I'm taking out all references to BPL.
It was just one aspect of many; a way to dodge one giant
hairball the FCC is about to cough up on us.
But when you say "BPL," a few people go into some sort of "brain lock."
They can't even hear anything else.
Oh well... back to building the 611 QSO transverters...

I am after any feedback good or bad to do with the Heil Goldline Pro.
If you have used this microphone with your radio what is your opinion on it
compared to the Goldline and other microphones of the same class?

Thanks

Much has been written and published on the net on this topic but just to add my two cents and perhaps summarize. I've had good luck with a variable HV DC supply. I bring up the voltage, albeit slowly, while monitoring current with a microamp meter. It's nice to watch the current gradually go lower, then I step up about another 50 volts or so then watch it go lower again until I reach the rated voltage of the cap. I let it "Cook" there for awhile then use the cap. There's a formula for the "Cook Time" based on the age of the cap. Do a net search for that one. Someone in G land I think. I have restored and recapped a lot of older HF radios this way and it has saved me a tremendous amount of cash.The new Electrolytics are a lot smaller/better but we're talking about five bucks each here. I wait till they show up at the Flea Market or local surplus outlet then scoop em up for .25 each. Oooops! Maybe I shouldn't have told you about that.

I have two Sangean ATS-909 receivers and was thinking of putting one into amateur radio service by using it with a small QRP (5 watt) transmitter. Is there any way of muting the receive functions during transmit periods? I would be willing to modify the receiver if necessary.

<< Heading sums it up. I'm using a 74HC04 to 'square-off' a sine wave, but it's causing a fair amount of ringing on the output signal's highs and lows which appears to be finding its way through to the eventual final stage. >>

Paul-

Others have given good advice. Ringing is due to reactance, whether it is on the power supply side or the load side of the chip.

Consider that the path between the 74HC04 and the following stage is a kind of transmission line that has inductance and capacitance. It needs to be terminated. I'm not sure how or if you can calculate the value of a termination resistor, but you should be able to do it experimentally.

But, how do you know when you have reached your goal if the measuring instrument introduces reactance? Perhaps measuring beyond the following stage will provide sufficient isolation, in addition to using short leads as others have suggested.

One other thought - would a plain 74C04 work at 8 MHz? If so, its slower speed might reduce ringing.

>terminated. I'm not sure how or if you can calculate the value of a
>termination resistor, but you should be able to do it experimentally.

I'm not sure what you mean by "terminated" actually. Do you mean it
must have its load connected when the measurement is carried out? If
so, this load which could be replaced by your suggestion of a
termination resistor, would simply constitute the input impedence of
the next stage, would it now? Hold on... are you suggesting that you
replace Zin of the next stage with its equivalent resistance in order
to eliminate any reactance present in that next stage? Is that the
idea? I'm afraid you'll have to indulge me a bit here as electronics
isn't really my field.

>But, how do you know when you have reached your goal if the measuring
>instrument introduces reactance? Perhaps measuring beyond the following stage
>will provide sufficient isolation, in addition to using short leads as others
>have suggested.

The short prods inplace of the flying ground clip certainly reduced
the ringing quite considerably. I'd be interested to know why a long
ground lead is a Bad Thing...

>One other thought - would a plain 74C04 work at 8 MHz? If so, its slower speed
>might reduce ringing.

Speed's quite critical to this application, unfortunately!

Hi,

Judging by the responses I read t your initial post, its clear that
things changed over the years.

I was on active duty on a baby tin can, i.e., DE-644, a Destroyer
Escort in the pacific between 1956 and 1958. During that time period
there were Radiomen, Fire Control Radar technicians, and ET's
(Electronic Technicians). We didn't have any Radarmen on board. It was
customary for the ET's to "sit" at the radars during general quarters
or at watch while underway.

Both of you gents should give a call to Mike Quinn Electronics --
(510) 569-1539. Failing that, check with Excess Solutions, (408) 573-
7045. If that doesn't work out, check with (brrrr!) HSC Electronics at
(408) 732-1573. I hesitate to recommend them because of their
unfavorable review on this page --
http://www.bluefeathertech.com/technoid/calswap.html -- but they still
do OK for small parts.

Good hunting.

> internet connection crashes.
==========
Perhaps not from a summer cottage ,but remote operation of HF stations has
been done in California and Hawaii
since the mid 90s .Access and operation is through a hand-held VHF radio.
Even a rotator can be operated remotely.
The brainchild of a aviator/engineer living in the Brea (California) area
it was/is called a Super-Station .
However in this scheme rx and tx are co-located.
The system was elaborately explained by its designer/implementor in 1995 at
a meeting of the Fullerton Amateur Radio Club.

I can understand that with antenna restrictions/ prohibition in urbun areas
and a possible emergence of BPL / PLC / PLT ,people are looking into
alternative ways to communicate on the HF bands.
Fortunately in a number of countries BPL et al has already been rejected by
the authorities , Japan and the Netherlands come to mind. I believe also in
the UK ,it is highly unlikely that powerline comms will be accepted.

ARRL's drive to block the introduction of power line comms in the USA ,by
means
of 'competent (engineering) reasoning' ,must be applauded.

2786. Means of building low quality receivers

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-18 21:06:36 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <bmsa1joqc1@news.oregonstate.edu>
Source record: 31702

I've been toying around with the idea of digitizing the entire AM commercial broadcast band and -- mainly for my own edification -- doing demodulation in a microcontroller or DSP. Although on one hand I'd claim I can then do cool things like AM stereo demodulation, on the other hand I do recognize such coolness is lost in that digitizing the _entire AM band at once_ from 550-1600KHz only allows me to adjust the gain of an RF amplifier to the point where _the sum of the signals from all the stations_ doesn't overload an ADC. In other words, this approach will only work to pick out relatively strong stations if I still want anything resembling a decent SNR, correct?

To get around this problem, then, I was thinking of using an NE602 mixer to select just the station I wanted and then following its output with an adjustable RF amp. If I go for the direct conversion approach, then, I can follow it with a variable gain baseband amplifier and still hear the weak stations with relatively good fideilty.

Is this a reasonable approach? Is it true that low (...to moderate?) quality receivers can get away with just feeding an antenna's output to a fixed gain broadband amplifier (or even just a matching/bandpass filtering network) followed by a mixer and _then_ an adjustable gain element? (As opposed to high quality receivers that appear to have tuned RF amplifier front ends?)

The idea of digitizing an entire band at once seems to look far less promising if your goal is to dig out weak stations...

Thanks,
---Joel Kolstad

(I also find it quite amusing to think I can build an evelope detector in software to test things out prior to building fancy synchronous detection routines!)

2787. Mixer products every 5kHz to 30MHz on DX-394?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-18 21:34:35 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <48ikb.8262$Z_2.605732@news20.bellglobal.com>
Source record: 31703
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

I was startled when I hooked up a DX-394 radio (RX2) to the output of the 2nd mixer of another DX-394 (RX1) to find that the strong MW station RX1 was tuned to showed up not only at the 2nd IF of 455 kHz but at every 5kHz from around 200kHz to 30MHz! The strength varied with frequency, probably in part with the gain vs frequency curve of RX2. There were stronger signals at the 2nd and 3rd harmonics of 455kHz. Had to reduce the RX1's RF gain to the point where its AGC was inactive and the receiver was operating just above its threshold of detection to diminish the forest to just a few trees.

The 2nd mixer is preceded by a crystal filter at the 1st IF of 45MHz +/-2.5kHz so I expected to see spectrum of about 15-20kHz width across 455kHz and some 3rd and higher order products like 910 and 1365kHz. The 5kHz interval is suspiciously the same as the steps in the 1st LO VCO frequency (45.150 to 74.995 MHz), controlled by a digital PLL. The 2nd LO at 44.545MHz +/-2.5khz is a varactor tuned VCO.

To generate products every 5kHz, surely we need a 5kHz signal or two very strong signals that are 5kHz apart going into the mixer or some non-linear stage after the 1st IF filter. Am I seeing something unusual or is this what I should see? If it's an anomaly, can anyone suggest what the cause might be? I'm thinking this is a fault or a design weakness that with more complex signals gives rise to a lot of interference to good reception. Could it be possible that this is the result of the method of observation and is not really occurring in normal practise?

How about some front-end selectivity using a varactor tuned circuit?
That allows for tuning under software control using a D-A converter.

A GE SuperRadio 3 could be used as a pre-built prototype. It uses 3
varactors (one for tuned RF stage) instead of 3 mechanical variable
capacitors. You could take either the tuned RF stage output or IF
output.

Have fun,
Jim

<< I'm not sure what you mean by "terminated" actually. Do you mean it must have its load connected when the measurement is carried out? If so, this load which could be replaced by your suggestion of a termination resistor, would simply constitute the input impedence of the next stage, would it now? Hold on... are you suggesting that you replace Zin of the next stage with its equivalent resistance in order to eliminate any reactance present in that next stage >>

Paul-

The next stage has some kind of input impedance, whether it is a logic gate or an analog amplifier. I'm saying that you may be able to adjust that impedance for minimum ringing.

If it is a logic gate, can you add a pull-up resistor across the input? If it is an amplifier, can you add a resistor across the input without upsetting the bias? Trying several values, you may be able to make an improvement.

Why is a long ground lead a bad thing? Because wire has inductance. Above some frequency it can no longer be considered a short circuit. The longer the wire, the lower the frequency. Your ringing contains frequencies that are multiples of 8 MHz.

In addition to keeping scope probe wires short, have you compensated the probe? Many scopes have a square wave calibration source available for checking calibration. Another thing you can use it for, is to adjust the probe for minimum overshoot and rounding of the waveform. (The adjustment allows you to make the scope's probe-to-input capacitance ratio the same as its resistance ratio.)

Fred

2796. Re: Mixer products every 5kHz to 30MHz on DX-394?

Tom
What is the spectrum going into the mixer at the output of the crystal filter? If this is OK, then it must be the second mixer that is at fault. Look at the spectrum of the LO into the first mixer - does it have 5KHz reference sidebands, and at what level?
What is the 1st mixer and post mixer amp? Are they able to cope with the strong broadcast signal? If they are not something substantial like a ring diode mixer and a strong post mix amp, then the IM might be happening there. A typical bipolar mixer might only be able to cope with -20dBm without overload. If the RF gain doesnt help, then maybe it is the RF amp that is at fault, though I wouldnt expect all this to get through the crystal filter. (though even crystal filters can be nonlinear if driven hard enough...)

Richard

Shouldn't you look at the TenTec RX320? It superhets to 12kHz and then does the final selectivity and detection in DSP. TenTec will modify old RX320s to bring out the 12 kHz IF to allow playing using a sound card (say DRM).

Or maybe the Software Defined Radio articles by Youngblood in QEX almost a year ago. He is selling card sets. A lot of his complexity is in a bank of switchable filters to cover the "zero" to 50 MHz range.

Or the Motorola "Symphony" chipset for AM/FM broadcast.

Or similar software radio chips from Visteon/Ford.

Or a paper in the Proceedings of the 1999 Central States VHF Conference* by Bob Stenowski, Director, Advanced Comm Engineering, Rockwell Collins. He pointed out that you would need an AtoD converter with more than 25 bits resolution/linearity to build a "DC to Daylight" receiver without frontend tuning / filters. He shows block diagrams of the Collins 95S-1A which covers 5kHz to 2Ghz, but has 9 bandpass filters to cover the range. The 5kHz to 30MHz range is upconverted with a variable LO to 51.2MHz and then handled like the VHF signals.

* available from ARRL

You have an interesting project.

<snip remainder of self-righteous indignation>

well, I have another perspective; did you ever stop to think that there
wouldn't be
such a prevailing anti-french notion if they would not only QUIT trying to
halt our
attempts to fight & end terrorism in the world, not only STOP being nothing
more
than a nation that uses the UN... (which, by the way, if you didn't know, we
fund
a quarter of the UN's budget; our total basic input, ASIDE of all the extra
few billions here and there we give, adds up to MORE than contribution of
France, Germany and Russian COMBINED?).... to thwart so many of our
righteous and morally correct war against the islamic extremists that, if
given thier
way, would have YOU killed? Did you ever stop to think that maybe if France
began standing up for herself and HELPING in this dreadful ordeal, along
with the
other sniveling weasel nations of europe, that we could wrap this up quicker
and
faster instead of them being a root cause of what is one of the darkest
periods
in human history to be stretched out FUTHER in terms of time and bloodshed?
Just what did all of France's attempts to thwart our removal of saddam and
put another knife in the back of terrorism GET them, huh? Another bomb in
Paris! And did you EVER think that that maybe if France finally began to
learn
her lesson about appeasement, along with all the other nations in Europe
that

had to bear the dreadful weight of world war II on thier backs, just *maybe* relations between that nation and a few others would improve with us? That just
maybe we would truly be the allies instead of this mass-perpetrated delusion
that we are already?

Kuddos to the axis of weasels for coming around on the last UN vote... I know
they didn't do it because of a change of heart, but at least it's a start in the right
direction. I'll give them *that* much. Now if they'll just open thier eyes and
wake up to the world as it really is and begin to help us, things will be much better
for everybody; Civilized Nations: 1, Islamic Extremist bloodthirsty murderers: ZERO.

Hi all,

I recently became interested in trying to build a small two-tube regen type receiver for broadcast and/or shortwave reception. I designed a simple chassis based on some vintage articles on the subject. This is the classic 'metal box with attched front faceplate' design. I was going to use cold-rolled steel since we have this at work and spot weld the face to the main chassis, but then I got to thinking that perhaps the steel might interfere with the coils. I noticed also after this that every old article that I've come across usually suggested aluminum for the chassis. They don't make mention of the reasons for this, however. I was wondering if ease of machinability for the amatuer working with simple hand tools, and perhaps also weight savings, were main factors, or was it mainly for lack of magnetic interation with the coils? We also have sheets of aluminum, brass, and stainless that I can use but I'm not sure if they can be resistance welded, so I would have to bolt the face onto the main chassis box. Anyone have any further ideas or insights?

thanks in advance,

Dave

Steel will be fine. Your suspicions about workability are correct but
there is also plating/painting to consider.

Aluminum is usually easier for most to work with with simple hand tools.
Steel is fine but it might rust and look bad after a while. Make the
chassie out of whatever kind of metel that you think is the best for you to
work with . Electrically there will be little if any differance.

Yes, I have found when building regenerative receivers wood is the best chassi. However a metal front panel is a must. However I only use battery tubes with low voltage. Never more than 45 volts. But when building solid-state regeneratives. A good ground plane helps. Build it the dead bug way.

Nothing wrong with steel. Altoid mint tin-plated steel boxes are very
popular for QRP projects, and tin-plated boxes are often used for
screening on commercial RF PCBs.

"Dead bug" construction means components mounted with legs up. I have not
seen this done with vacuum tube projects.
More important than the chassis material is that ground connections come to
a common point rather than scattered about the chassis.

My first Heathkit radio used copper-clad steel. I think this is a great combination for electro-magnetic shielding from low frequencies where you need the ferrous material to high frequencies where you need the highly conductive copper skin. Galvanised steel isn't a bad choice either. Steel is needed if you use the radio in the vicinity of CRT's, computers, etc.

Good luck,

Tom

Hehe, don't feel too bad. I have zero experience with solid state stuff, so when I was told to build my trial projects in DBSF format, I was left scratching my head. I laughed out loud when I was shown a "Dead Bug Squashed Flat" project. This is your components laid out flat on a perfboard and the wires run straight, point to point. It really does look like a DBSF!!

I'm not sure how to do the tubes in a DB format, but everything else should be straightforward.

"General Radio" used to sell tube sockets which were surface mount with side terminals. I've looked high and low for some of these, but haven't had any luck. They'd be ideal for breadboard tube projects.

cheers

Your articles aren't old enough. After real wooden breadboards went out of style, metal chassis were cadmium-plated steel. Aluminum chassis didn't appear in wide ham use until a few years after WW2.

Nowadays I prefer using PC board for mounting components. The Al chassis being upside-down used as a shielded base. In many cases the smaller components can be just soldered together in "basket weave" construction supported by the ones that need to be soldered to the PC-board ground plane. Decades ago Pete Sulzer did his prototypes in full basket-weave style without a ground plane - but few people can visualize ground loops well enough to build RF circuits that way. When you visited his company you'd see his prototypes hanging from nails on the wall.

For air-dielectric capacitors: two plates one centimeter on a side, separated by one centimeter equals one picofarad. That's forgetting fringing and other edge effects.

And of course, everyone did use steel (once things progressed beyond
wood and bakelite chassis) right up until aluminum because readily
available and/or cheap enough, at which point I doubt anyone used
steel except if what they were building was really really heavy, ie
a kilowatt modulator or final.

John Bartley (jcb@igs.net) writes:
> I'm not sure how to do the tubes in a DB format, but everything else
> should be straightforward.
>
I'm not sure it completely translates to tubes, since "dead bug" seems
to suggest everything mounted on one side of the circuit board.

But people did take advantage of copper circuit board in tube circuits.
Invert the chassis, and use it merely to protect the circuitry.

Sometimes the tubes were mounted with a bracket (made of more circuit board,
and even soldered to the main board) on the copper side of the
board, the most obvious times were when the tubes were Nuvistors, but the
scheme was used sometimes when compact construction was desired. But usually,
the tube sockets were mounted in holes in the circuit board, and if aluminum
is easier than steel to work with, copper circuit board is even easier.

Once the tube sockets were in place, then everything would be wired up
as usual, with the difference being that it was really easy to drill a
hole for a coil, and every time a ground point was needed, it was a simple
matter of soldering the lead to the copper circuit board. No high wattage
iron or gun is needed, since the copper isn't really thick. If you need
to change things, it's relatively easy to disconnect that ground point,
and unlike with old methods, you don't have an extra hole if you do change
it. Leads could be short, because you could make ground connections where
they were needed rather than where there was a ground lug.

Because of the tube sockets, this tended to be a bit more formal than with
solid state devices, but it was still a neat way to build, and some of the
most busy builders used it because they were always trying to improve things.

Frank Jones did a lot of this sort of thing, at least after Nuvistors came
along. Even before that, many of his converter projects were built on an
inverted chassis, with a piece of aluminum for mounting the parts rather than
circuit board.

Bill Hoisington K1CLL wrote tons of articles in the sixties ane early
seventies, and pretty much everything was build on circuit board. He was
not concerned with looks, and the few times there were photographs, they
did look very "dead bug" like. He even built an amplifier with a 4CX250
or such on copper circuit board.

Wow this is some really great info! Thanks Jim and to all others who took
the time to respond!

On a side note - I was trying to join the "Glowbugs" mailing list that I've
seen mentioned on a number of web sites, but I havent gotten any responses
to my to "subscribe" emails. Is this a dead list? If so, are there any
similar current alternatives?

On a second side note - does anyone happen to know what the formula would be
to calculate the capacitance between two metal plates of a given area and
given spacing, having an air dielectric?

thanks again to all!

Dave

Only one problem I ever had with a steel chassis was a project that used a rather sizable power transformer. The transformer induced currents into the steel chassis that caused metering problems. It was corrected by using a single-point ground to the chassis.

Steel chassis were the norm for much of the tube years, commercial and amateur.

Indeed, yes. As a youngster, a number of my tube radio and amplifier projects were built on cookie tins - thin tin plated steel (I lived in the UK where we called them 'biscuit tins'.) No adverse effect on coils in cans, nor on the open coils of an early TRF/regen experiment (about an inch off the chassis, IIRC.) When done, slip the tin lid on the bottom and even a flat cookie or chocolate tin becomes quite stiff. If they tend to "oil-can", just put wooden posts (dowel) in between top and lid.

A big advantage was the ability to solder good ground (UK "earth") connections with a 25 watt iron without getting cold joints - fine for audio and BC-band AM. For an FM tuner project I soldered little 'tin' fences at strategic points and paid more attention to the ground points.

Cheers,

Roger

I assume that remark stems from the fact that you live in one of the
yellow-bellied gutless coward nations over there. Hey, here's an idea;
why don't you guys start demanding your leaders quit bowing down
and kissing the rear end of terrorists and middle eastern dictators? Just
how can you *stomach* to live in a nation that just sits around and
gets hammered and attacked and blasted instead of standing up for
yourself and doing something about it? Or is making remarks about
newgroup people having no brains simply *safer* because you're
on the other side of the globe at a computer terminal and the terrorists
are right up in your face?

You'll have to excuse me, I just can't fathom why anybody would
take the path that you guys over there have. Perhaps that is why europe
is slowly being left behind economically in the world and the shift of
industrial & economic strength is headed away from you guys and towards
eastern asian nations. I guess they'll be the future, if you're going to be
*the
past* in your hemisphere.

One thing I noticed on first trying circuit board as a "chassis" for
tubes was how hot the very thin layer of copper became. Until then, I'd
taken for granted how effective a solid aluminium chassis is at
conducting the heat away from the tube sockets and getting rid of it.

Last time I needed them, I used 51K's in series instead.
Don't ask me why - I don't know - but I had a tough time
finding 100K's, but no problem finding 51K's.

I have seen a few nice layouts on Brass chassis, as well. Easier to
work than steel, and you can still solder to it. I built some tube RF
decks on 1/16" brass sheet stock, and mounted them into a steel cabinet
years ago.

One thing to watch out for. Relay sockets are not made to run at
high temperatures, so you have to make sure they don't melt or burn.

Yikes!!!!!!!!! Wherever are you going to find temperatures in a receiver
that would melt any plastic?

Polystyrene miniature tube sockets were used in "UHF" radio receiving
projects. Soldering to their contacts took some skill to avoid melting the
plastic, but there was no problem during operation.

I'll grant you that transmitting firebottles might bother a polystyrene
socket.

That was what I was thinking. Someone trying to use a sweep tube to
build a small transmitter, and having heat problems with the socket.

2830. Re: Ringing on square wave: how to eliminate?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-20 09:27:18 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <vp7ak1lvnrkd02@corp.supernews.com>
Source record: 31647

An oscilloscope probe has capacitance between the probe tip and ground connection. Any inductance in series with this path makes a resoant circuit that rings when hit by a fast transition. I highly recommend reading Tek's "ABCs of Probes", which you can get at

http://www.tek.com/Measurement/App_Notes/ABCsProbes/60W_6053_7.pdf

It mentions the phenomenon on p. 10, but it would be very worthwhile to read the whole thing.

Many thanks, Roy. I will. I really need to get better acquainted with
these finer points.

Hi everyone I have made a power supply for my rigs

The schematic is the typical regulator with power transistor wrapped around it for the extra juice.

I need 40 amps continues ..

I tried 4 mj2955 which are rather nice for foot warming in the winter .

I also tried nte-180 which are very good. is there anything better at a logical price

I would like to keep the number of transistors down to 1 or 2.

Can someone advise my on what to use for power?

The function of the pass transistor is to dissipate as heat the difference between input and output. Sounds like you need a bigger heat sink...or build a switching supply.

Hi, check this link and see what you need to do,
one or two pass trans. will not do the job for you,
easier to use 6-10 pass trans to share the load.

http://www.mitedu.freeserve.co.uk/Circuits/Power/1230psu.htm

Is your transformer able to supply necessary power to this supply ?

regards,
clarke

> The "dead bug" way? I'm not sure what this means - please forgive me I'm
> new to this :-)
=========
This is a method of construction where components are soldered to unetched
printed circuit board islands (made with a special rotary bit which only
removes a thin ring from the copper surface) or to insulated PCB patches
glued onto the unetched PCB ,with ICs glued to the PCB with the legs up
(hence dead bug) and connected to other components .
If permissible ,additional 'connecting points' are achieved by soldering
high value resistors (a number of MegaOhms) perpendicularly onto the PCB
with the other end serving as the connecting point.

It is also called ugly construction . Extensive info on these methods is
given in an excellent book for homebrewers :
"Experimental Methods in RF Design" Chapter 1. ; published by ARRL.

If you want to keep it to a couple transistors they would be expensive.
You are better off using either more NTE-180 or more mj2955, but I would
cut the voltage down to around 18 volts instead of 24 volts as this
higher voltage leads to more heat for the transistors. Rob

These surface mount sockets have substantial screwed connections and are
made of PVC which as suggested might not be the optimum for VHF applications
,but also might not be able to cope with the heat produced by the relevant
valve (tube), especially when the valve is of the medium to high power
variety.

==========
Talking about nails ,some time ago in the dutch amateur radio mag.
'Electron' , there was an article describing a kid's radio.
,dubbed 'Nail Radio' . Its construction was on a piece of timber into
which copperclad nails had been hammered in circuit diagramme configuration
. The components (for this medium wave receiver) were subsequently soldered
to the nail heads.
A superb way to introduce newcomers to electronics and radio home-brewing.

The PIC STV5730A on screen display project board provides a simple platform for the development of microcontroller driven text over video applications. It is ideal for creating on screen displays for ATV applications such as callsign generation.

For the non-programmer a PC keyboard interface version allows easy creation of on screen displays.

The PIC STV5730A on screen display project board is available from http://www.STV5730A.co.uk

Features:
* 16F628 microcontroller for flexible development
* STV5730A on screen display IC gives 28 character by 11 row screen
* 128 text and graphics characters defined in ROM
* Text over video or self generated video signal
* 10 i/o lines on the 16F84 for easy interface to sensors, keypads, etc
* Power supply 5V dc or 9 - 12dc via on board regulator
* Free PIC-STV5730A demo software in assembler & BASIC
* Screen display routines available
* Simple PC serial interface, ATV callsign and GPS display examples
* Enclosures available
* Accessories and connecters

Cut out the tedium of project development and get straight to the fun of making your idea work with proven hardware and well commented easy to understand example code.

Assuming that so far you have only considered bi-polar transistors ,perhaps
it would be beneficial to look into the application of Power MOSFETs. In the
'on' state they have a very low resistance ,hence at high currents they
dissipate less heat .
Consequently you would need smaller heat sinks.

Source record: 31665

Thanks for the responses so far...

The idea of digitizing the entire AM band would be a lot more appealing if someone made one of those small serial interface ADCs that had a sample rate in the 3-4MSps range. The best I've found so far is a 1.75MSps from Analog Devices (AD7470, a 10 bit ADC), which -- even restricting the AM band to the 'traditional' 550-1550kHz instead of the slightly expanded 500?-1710kHz -- obviously isn't adequate to sample the entire 1MHz spectrum.

Hence I think I'm going to try an approach along the lines of a micrcontroller's PWM output feeding a Linear Tech. LTC1799 square wave oscillator, filtering its harmonics a bit, feeding it to an NE602A mixer followed by a (means yet to be determined) adjustable gain IF amp, and then the ADC on the microcontroller. For the audio output I the TI TLV320DAC23 is a high quality stereo DAC with built in 100mW audio amplifiers and serial microcontroller connectivity.

Of course this is all going to have to fit into an Altoid's tin, right? :-)

Heathkit Digital Trainer AC powered

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=2566410867
This is a working Heathkit trainer Model ET-3100 with such things a
Power supply with Positive control knob and negative control knob.
Connetor blocks to make solder less connections. A 1 k ohm contol knob
. this is a variable resistor for your experiments. also a 100k ohm
knob for the same. Breadboarding board to make solderless connections
. A range switch to selects the frequency range of the signal
generator. (low or High) A frequency control knob = varies the
frequency of the signal generator fromn 200hz to 2khz. connector
blocks for sine gnd and square wave.. Red led for unit power on
indicator. Two large schematic sheets for the trainer are included. A
GREAT GIZMO FOR A ELECTRONICS ENTHUSIAST. Shipping in the USA is
$13.00 Canada is $17.00

Such designs are simply brain dead.

If you need +12 V at 30 A and you are using NPN series pass
transistors, you should use about 13 V at the end of the capacitor
discharge cycle. This should be doable with far less than 24 V
capacitor nominal voltage.

Assuming the capacitor voltage drops from say 17 V to 13 V during each
half cycle, the power dissipation in the series pass transistors will
be ((17+13)/2 V)-12 V) x 30 A or 90 W, so this is doable with 3-6
transistors.

However, the required base voltage varies between 14 and 18 V, so a
separate power supply is required, either with a separate secondary
winding or by using some kind of voltage doubling, but this needs to
supply only 2-4 A.

The other alternative is to use PNP series pass transistors on the +12
V side, in which case a high, separate voltage is not needed.

>> Consequently you would need smaller heat sinks.

>dont have any idea how to work with mosfet

In this particular application - pass transistors in a linear regulator - I don't see that MOSFETs would have any particular advantage.

It's true that modern power MOSFETs have a very low series resistance when switched "fully on". This allows for low losses, and relatively low heat dissipation, if they're used in an application where "fully on, or fully off" is suitable. "Hard" power switching, or pulse-width-modulated drive applications such as a switching regulator or a DC motor-speed controller are good places for MOSFETs (or IGBTs).

However, a linear regulator isn't this sort of application. In these regulators, you aren't driving the pass transistor "hard on" - because, if you did, the regulator would simply pass the full input voltage to its output and wouldn't regulate at all! Instead, you're switching the transistor on only partway, so that it's passing only the amount of current needed to "pull up" the outputs to the regulation voltage.

The rest of the voltage (input minus output) is going to appear across the pass transistor (and possibly one or two other components in series with it, such as ballast resistors) and will be dissipated as heat. This will be true regardless of whether the regulating element is a MOSFET, bipolar transistor, or whatever. If you're sucking 30 amperes, and dropping 10 volts between input and output, your pass elements will be dissipating 300 watts.

The only ways I know of to reduce the heat dissipation are to either lower your input voltage (but not enough to cause the circuit to drop out of regulation), or move to a lower-loss architecture such as a buck-mode switching regulator. The latter can be quite efficient (often 90% or better), but you have to work REALLY HARD to build one which won't emit enough radiated and conducted RF switching noise to totally yngvi up your HF reception.

I agree with the other posters, who suggest that it's probably preferable to use a sufficient number of simple, easy-to-buy pass transistors (2N3055 being the classic example). Use enough

so that you can use 'em well within conservative ratings - don't
go anywhere near the edge of the "safe operating area" - and
ballast them so that they share current properly.

The main reason I wouldn't use a 2N3055 in that application is the
gain falls of dramatically at high Ic. Design needs to accommodate
this in terms of both driver current capability and loop gain.

Someone mentioned the 2 to 4 amps of base current you'd have to supply for bipolar pass transistors. You wouldn't need it if you used FETs. I'd look seriously at P-channel VMOS for pass devices, myself.

The USA has supported many butchers in recent history and the US even
supported and turned a blind eye to saddams own buchery when he served
the US and their will. Lok up most of the evil dictators of the last
50 yrs and you will find either open US support of their crimes or
clandestine US help thru the cia.

The US governent backed regimes in Guatemala that killed over a
hundred thousand people.....
We supported the coup that put Sukarno in power in Indonesia and his
government killed over 500,000 innocent people all the while the US

still gave its full support.....
Pinochet in Chili...remember him.....another US installed president
who killed thousands upon thousands of innocents.....
Noriega.....yep we supported him for many years before he US finally
had to take him down......

There are more...look them up.....all these people were allowed to
kill innocent men women and children because they served the US
interests in their countries.......Saddam was allowed the same
liberties....he killed and maimed with impunity all he while the US
knew what was going on.....only after he ceased to be usefull to the
USA.....was he expendable.....

I have no problem with France staying out of Iraq.....they had
monetary losses to consider.....had the US had any monetary or
political interests in Iraq Saddam would still be free to butcher his
own people.

I find nothing funny in french people dying in a heat wave......anyone
who does is clearly a fucking asshole.....

>
2N3773 are better still (check out current).

If you want a power supply to deliver round about 40amps the the first thing to remember is that you MUST have the correct amount of pass transistors to handle the current.
If you use 2N3055's (very good and cheap) you will need at least 10 of these, don't think for one minute becouse you see the current stated as being 20amps that one transistor will be able to handle this amout of current, it won't, it does not work like that.
The best you can hope for (current wise) from one 2N3055 is FIVE AMPS. So for a forty amp supply you would need at least, eight and a couple for that le-way we all try to allow.

One other thing you must have good heat sinks.

Regards the transformer, it should be able to handle the current and should (ideally for a 13.8Volt supply) be rated between 17.5 and 18.5 Volts of load.
Once regulated this voltage will rise to about, 24 Volts + or - 1 or 2 Volts.

Regards regulation the most common way is to use the LM723 voltage regulator chip complete with short circuit protection.

Smoothing caps should be another point of concern.
Try to find two large ripple handling units rated at about 40 Volts and allow two thousand mfd
per one amp of current required.

One final point to remember when building your own power supply is to use some form of ELECTRONIC OVER-VOLTAGE PROTECTION (I.e., the MC3423 chip is perfect).
The number of cheap commercial power supplies on the market without overvoltage protection fitted is a crime (but they never tell you this in the Ads..right..?.).

Hope the above helps in some small way. Good luck, Ken, G4KIR.

The current gain, Vbe and Vce are all awful at higher currents. For instance, the current gain is specified at 4 A only. For 40 A, you should put ten devices in parallel and still have to design for a worst case total base current of 2 A.

Even with Ic=4 A, the worst case Vbe is 1.5V and apparently a lot more on higher currents. If you are going to supply the base drive from the same rectifier as the main output current, the voltage margin between the capacitor voltage and output voltage must be quite high, causing a lot of power dissipation.

High capacitor voltages and high power dissipation and thus high temperatures are nasty things if some of the transistors fail.

Have to agree, the US has supported many of these people in the past.
Whether the US finds them expendable at some point, I have yet to decide. To
me, it looks more like they come back to bite US in the Ass. We even dealt

with Afghanistan not too awfully long ago, giving them Fire Power to defeat the Russians(?). It has never failed. We've always had to retrace our steps and take down those we've helped for whatever reason and in cases of war, MANY of our weapons were found - why? - because we supplied them!

What we need to do, is keep our noses out of their business.. Defend our borders vigorously.. if anyone comes to screw with US, wipe them out - no questions asked. As to the rest, mop up after they are done! They are all creating Genocide when they are allowed to fight amongst themselves for years.. Surely, they can't create children fast enough to replace all the losses if allowed to kill thousands at a time. If they want to kill each other off, why the hell should we care? While, I don't like to see any one die, WE CAN'T STOP IT. WE can NOT be the world peace keepers.We get one done, another starts. It is a LOSING proposition and WE the tax payers are paying out our ass for it. OUR soldiers are dying for it. Our own infrastructure has severe problems and our people are being taxed to death to supposedly fix those problems, yet they continue to grow.. TAKE CARE OF US - TO HELL WITH THE REST. FOREIGN AID SHOULD BE CEASED. MAKE them borrow like WE do.
Quit supplying these people like a bad habit and see how fast the shit stops. WE are the ones funneling the money!

I'm not taking sides in this issue here, just using it as an example.. The Middle East.. Israel, Palestine, etc... That region has had war since biblical times... WHO ARE WE to think we're going to go in and stop it in a few months to a year or more? It hasn't worked and it isn't going to. WE can't brain wash those people into giving up. They've got a seemingly inbred hatred for each other or others and NOTHING will stop them from their feelings.. WE have funneled cash on top of cash for them to "woo" them into peace and it has NOT WORKED.

Funny, Saddam had all those look a likes.. Since the war, we've not seen a one of them OR HIM. WHY? Surely they couldn't all have escaped. SOMETHING STINKS. Same with Oscummy Bin Laden.. Our country has some of the best intelligence and we can't find him? Yeah right. Maybe we don't "want" to . He(?) and now Saddam is good for getting tapes to Al Jazear.. Why not plant someone inside and trace them back! Don't we have a spy or stoolie we can plant at the station or nearby? Sure, they don't deliver tapes every day but hey... they track drug traffickers for years sometimes... If you want them bad enough, you'll do what it takes. Personally, after 911, we shouldn't have pissed around with a war, we should have just nuked the damned country.. THAT is a no miss approach. I'm not into seeing people die BUT if they come after US, then all bets are off in my book.

Another thing that pisses me off, is Kuwait... WE liberated them from Iraq in the first war. Some of them have turned on US since. That is the thanks we get. They were one of the countries who boosted Oil prices not long after that as well. THANKS A LOT! WE ALWAYS get bit in the ass when we neb in. ALWAYS. AND what REALLY pisses me off, is that OUR tax dollars are supporting the bombers of the 1st WTC bombing. They are eating 3 squares a day with a roof over their heads, heat, medical when many of our OWN aren't

1/1000th as lucky. That did NOT stop their brethren from trying it again. WE should have tried them for war crimes against the US and they should have been SHOT. THAT is how you cure a disease, with an Inoculation. Right between the eyes.. Not to return again. SHOW these assholes we won't tolerate it - by brute force and they'll quit screwing with us. NO.. we pussy foot around with them. The Civil Libertarians are going to be sorry one day. These murderers will kill them just the same and think nothing of it. I can assure you, if one of Saddams men walked into the ACLU offices with an Uzi, they'd be shitting their pants wishing for the Army or whoever else to arrive.

I was at Lackland AFB a good many years ago. A man from another country was on the base for Political reasons. He allegedly raped a female Airman. A group of the guys wanted to rip his head off. They told the CO and in turn were told NOT to take action - that THEY would end up in Leavenworth.. That this guy had Diplomatic Immunity and couldn't be held even if we wanted to. REALLY???? If that were one of US here IN the US, we'd be in Jail, like Kobe Bryant MAY be IF found guilty.
I heard today, he could face a minimum of 20 years! IF we went to THEIR country, we may be executed or jailed and never heard from again. WHERE IS THE JUSTICE???? WE KISS THE ASSES of these other countries. WAKE UP PEOPLE, ENOUGH IS ENOUGH. It is TIME to start taking care of US. In cases of War, I don't want to see innocent people die, but these bastards have shown, THEY do not play fair. SO WHY SHOULD WE?

What do you consider 'reasonable?' Electronix Express has 4 digit 0.5"
numeric LCD displays for $3.95... http://www.elexp.com/opt_lcd1.htm .

You'll always be able to find examples of high volume consumer goods that
are cheaper than the parts alone in low volume... which of course suggests
that -- depending on the labor necessary -- sometimes it might be cheaper to
disassemble perfectly good new equipment to get the goodies you want!

Hello there,

I'm looking for used CSI Brand LTR (trunking) controllers you may want to sell or trade away. The specific models are the 4200 and 4900 units.

If you have a TP-163 tone panel, I'd also be interested in talking with you to sell or trade.

Email me off the www.radiowrench.com web page and I'll get right back with you. You can also take the NOSPAMPLEASE out of my Email header below to contact me.

thanks
skipp

skippNOSPAMPLEASE@pilotNOSPAMPLEASE.ucdavis.edu

http://www.radiowrench.com has an Email icon that works well.

cheers...

Cheap enough for me.

I don't recognize the source. Are they a surplus reseller so that continued
availability is questionable?

Thanks for the info.

> Hi,
> I need to order crystals for old transceivers Systcoms VTR-10 and VTR-12.
> What is the equation formula) for calculating crystal frequencies ?

<snip>

The formula will be different for different manufacturers,
depending on how they designed their hardware. Example: Some Motorola
portables used a 10.7MHz IF, while others used 45MHz. This, obviously,
had an effect on the crystal formula.

International Crystal (http://www.icmfg.com, I'm assuming that's
who you're talking to) may have references to your particular
equipment's model. Check with them first.

Failing that, you will need the service manual for your equipment.
The crystal frequency calcs will most likely be listed in there.

Good luck.

Can anyone direct me to some good understandable references on single sideband frequency modulation? I have no real practical reason for wanting to know about this. It is interesting to me in a "mathetical" sort of way. Of course, that is dangerous for me because my brain gets very stubborn when I try to do math. Such ideas as "negative frequency" kind of send my mental faculties into total shutdown.

But I read schematic very well. It is a visual language I can usually understand. Seems like years ago there was an article on SSB FM in Ham Radio. That would probably be a good start. If anyone can send me a copy of that article I would be much appreciative.

Thanks in advance

>for bipolar pass transistors.

Good point. The base current wouldn't be wasted (it'd flow into the load), but the need for a fairly high-current driver would certainly complicate the circuitry and require the use of a higher-voltage transformer and unregulated supply, compared to a MOSFET solution.

> You wouldn't need it if you used FETs. I'd
>look seriously at P-channel VMOS for pass devices, myself.

Might be even more advantageous to use N-channel VMOS, and regulate on the negative side of the load. N-channel power MOSFETs are significantly less expensive than the closest P-channel equivalents, and there seems to be quite a bit more choice in terms of size and rating. If I recall properly, the charge-carrier mobility in an N channel (electrons) is a good deal higher than in a P channel (holes), which means that N-channel MOSFETs can have smaller channel areas than equivalent P-channel devices, hence more dice per wafer, hence lower prices.

No such thing that I have ever heard of.
For an easy explanation of the modulation modes -- see URL:
http://www.williamson-labs.com/480_mod.htm

Perhaps you were thinking of commercial FM broadcasting -- there is a
baseband FM signal, a 19kHz pilot carrier, and a DSB suppressed signal at
38kHz.
All this yields stereo FM
Baseband is left plus right channel
the DSB signal is left minus right -- so after demodulation, adding them
gives Left and Right channels

No, the January 1977 issue of Ham Radio magazine, it was the
cover article. (I knew it was a January issue, and around that
time, but I used the online index at
http://webhome.idirect.com/~griffith/hrindex.htm
to find it, though it took a few tries to figure out which
category it was in.)

I could never really make sense of the article. My recollection
is that it didn't do a good job on conveying the theory to
the average ham, or even the purpose of such a mode, and then
went into some stuff about implementing using some circuits out
of a textbook and not a complete circuit. One or the other
would have been fine, but in straddling both theory and practical
it did neither well.

I believe they're new; I base this on their _not_ being in the 'surplus' section of the print catalog. EE's primarily target appears to be the educational/hobbyist area (i.e., basic electronic components at 'reasonable' prices, lots of kits, test equipment, etc.) I've never ordered anything form them, but have gotten a couple of catalogs (they're >300 pages -- quite extensive, really) over the course of a few years so it looks like they're here to stay!

I would think it would be for the same reason as SSB for AM? To achieve half the bandwidth utilization for a given signal? (But at the expense of 3dB poorer SNR...)

I suspect that going through the math for the 'direct generation' means of SSB-FM would be pretty gnarly, but the 'first generate FM, then add a sharp filter' approach should work (although this will really generate vestigal sideband modulation...).

^^^^^^^^^^^^^^

It occurs to me that this part of my comment is non-sense given the machinations one has to go through to compute SNR through an FM channel anyway. Sorry. One wonders what the SNR degradation _would_ be, however.

I would have to agree, that it is the reference sidebands of the LO that you are seeing.....it sounds like they are using a relatively wide loop filter in the synthesizer, in order to achieve a fast settling time.

2880. Re: Mixer products every 5kHz to 30MHz on DX-394?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-22 02:45:26 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <hZIlb.3104$aw5.237992@news20.bellglobal.com>
Source record: 31597
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

Because both radios are the same design, I suppose it's possible that what I am observing is as much the fault of RX2 as it is of RX1 except that the output of RX1 at 455kHz only drives RX2 to about S9 while the test signal into RX1 drives it much higher. I wish I had a spectrum analyser. I might be able to confirm that the effect is or is not the influence of the second RX2 by checking the output of RX1 with my boat anchor analog R4B - it cannot receive 455kHz but I was observing the effect with RX2 tuned to the 10m ham band, too.

The DX-394 comprises a 3SK195 RF amp, double 3SK195's for the 1st mixer differentially driven by the r.f. amp and in common mode by the 1st LO, 45MHz crystal filter, 2SC27140 1st IF amp, 2SK210Y 2nd mixer, diode switches for choice of two filters. The 1st LO PLL is a Fujitsu MB87014APF-G-BND referenced to a 33MHz crystal all under a soldered shield. From the schematic, (I'm no expert at reading these) pin 12 (designated as the output for an active type low pass filter) feeds what looks to be a control for voltage applied to a varactor diode with a feedback path consisting of a 33k in parallel with a 0.01 (M - mylar?) cap both in series with a 0.033 (M) cap. That would be the low pass filter and would control settling time, right?

It's been quite a few years since I looked at the article. There was
just something about the article that seemed like I'd been dropped into
something. Maybe the style was different from most articles in the
magazine, maybe because it didn't really seem to be a practical article.
There just seemed to be something missing. Yes, it would take up less
space, but then why not go to some other mode? It's the only time I've
seen something on the subject, and I think it could have better been handled.

Fair enough. If the idea were to conserve bandwidth, you'd probably be using narrow band FM anyway at which point SSB-NBFM takes no less bandwidth than convention SSB-AM and... it _might_ even have worse SNR, although I don't know calculations off-hand. Hence I suspect that SSB-FM is nothing more than a curiosity... could be fun to implement just for the sake of experimentation once we're all running software defined radios, though!

From your description it sounds like someone was excited by the novelty of the idea but ran out of steam before actually implementing the idea!

as i understand, the fm signal, due to its nature of changing rate of phase change generates a number of sidebands. Filtering these sidebands would mean that a band-pass filter is being applied to the fm signal. That would amplitude modulate the signal as well. Amplitude modualting would create some more sidebands but within the filter's band-pass.
Finally, we would arrive at a 'least-bandwidth' signal that would resemble SSB. So you might as well expend five crystals (for a ladder filter and an oscillator) and get good ol SSB going.
A more intiutive example would be to consider an FM signal being modulated by a single tone. That would waver the carrier back and forth around the center frequency of the carrier. Now, if you passed this through a band-pass filter, you will see the amplitude drop off at the filter's skirts. This will resemble an amplitude modualted signal. depending upon the filter bandwidth, you might see either an AM, or a two-tone (carrier center being one, the modulated tone the other) SSB signal.
I may be completely missing the point though, i welcome an explanation.

I think you have a point here. Removal of one side of the set of sidebands turns the FM signal into a sort of AM/SSB signal. During transmission, FM's robustness to impulse noise will be lost. The presence of a limiter in the receiver, will turn the signal + noise back into a corrupted DSB FM signal for demodulation.

It sounds like there is a single pole (second order) filter/PLL system. The whole system would have to have a loop cutoff of 1/20th to 1/50th of the reference freq (100-250Hz) to get reasonable sideband suppression. You could try looking at the waveform on the VCO control line - if the 5KHz signal is more than few mV then there is probably something wrong. Try also putting an attenuator in front of the RF amp - if the problem suddenly disappears with increasing attenuation, then the problem is overload

This would appear to depend on how sharp the skirt of our hypothetical SSB (really VSB, now) filter is? I.e., at low carrier deviations there's some AM and therefore it's not _quite_ as robus, whereas at higher carrier deviations the filter would be nice and flat and look just like regular FM in terms of amplitude.

After all... in the presense of some AM on regular double side band FM, most receivers still perform just fine, don't they?

Indeed.

One interesting commercial system out there is the Motorola C-QUAM (compatible quadrature amplitude modulation) stereo method, used in the US for commercial AM stereo broadcastings. Since it has to be backwards compatible with envelope detector-based AM receivers, the resultant output is -- I would suggest -- something similar to amplitude modulated phase modulation! (I think it's actually quite clever...)

Is it just me, or does it seem like American semiconductor manufacturers discontinue any chip that isn't selling so fast that it requires a new fab to handle the production? I'm beginning to wonder if there's enough paper in the world to publish The Handbook Of Useful But Discontinued US-Manufactured ICs.

I can see where some didn't sell well enough to warrant much more than an occasional run of a hundred thousand or so. But hell, the other day I found a tube of zero-crossing switch ICs in storage and Googled on the part number, and it looks like there's enough demand for these things that I could get well over $600 for the tube! There's a listed substitute, and *it* is obsolete too (and selling for over $13 a copy from those who have them). How can they say something like this is not worth keeping in production?

Its simple. MBAs run businesses, not people who understand the
business, and their customer's needs. They only care about ROIs, and
know they will be gone before they ride the company completely into the
ground. The government doesn't help. High taxes on inventory cause
leftover and obsolete parts to be written off. the paperwork required
to liquidate obsolete parts can exceed the value received by selling
them, so they go from the stockroom into a landfill.

Bill, I just dug out the 1977 issues of HR from storage and looked
the article over. Author Richard Slater (W3EJD) said almost the
same thing at the end of the article on page 15 under "closing
comments." The nomenclatures for different modulations were
formalized by the ITU-R since then but the FCC still doesn't have
anything covering this "single-sideband FM" modulation type for
U. S. amateur radio.

A general problem with understanding the concept is the simplicity
of the explanations of AM in today's amateur radio. The mathematical
representations of all modulations have been known and distributed in
text books for decades...my introduction to that was "Electronic
Designer's Handbook by Landee, Davis, Albrecht, McGraw-Hill 1957,
Section 5. Those who can follow the series expressions in a
summation formula, study it, will understand how a phasing-type SSB
modulator and demodulator can work. It is much harder to look at the
expressions and "see" FM or PM; Hewlett-Packard's Agilent site has
a neat little animated Java display that may help some on that.

Filter-type SSB from AM is almost intuitive when the AM spectrum is
shown. That is easy to comprehend...once all accept that the content
of each AM sideband has the same information. (there are still some
long-timers who refuse to accept that the carrier RF energy doesn't
change in AM at less than 100% modulation, heh heh) FM and PM
sidebands are definitely NOT easy to visualize since their individual
amplitudes and phases change depending on modulation index and

modulating frequency. There isn't any corresponding similarity of FM and PM to AM for the repetition of sidebands' information when looking at the spectral content.

What Slater was discussing in that January 1977 HR article was what a group of researchers had already been doing in the early 1970s to see if there were alternatives to SSB-like frequency multiplexing in multi-channel circuits. Part of that investigation was to get around some of the patents still existing on frequency multiplexing via single sideband techniques (pioneered first on long-distance telephony, by the way). Another part was to simplify (if possible) the circuitry involved when carrying a LOT of channels. Equipent of 3 to 4 decades ago was a lot bulkier than it is now for non-digital multiplexing. The "narrowband" necessities of working in small-bandspace amateur bands was not a prime criteria for that research.

Slater explained much of the above in that article and didn't claim any exciting narrowband results of previous art. The (mislabeled in my opinion) "single-sideband FM" technique of combining FM and AM is simply a DIFFERENT way to communicate information.

A truly different way of modulation exists in everyone's telephone line modem that can send/receive up to 56 Kilobits/Sec in a bandwidth of only 3 KHz. That is a combination of AM and PM. That isn't intuitive to AM-oriented minds and there still exist arguments in newsgroups that such high rates "aren't possible!" :-) Yet most of us POTS users with computers regularly get 33 to 56 KBPS rates over 2.5 to 3.0 KHz bandwidth telephone circuits.

I've not seen much on that "single-sideband FM" stuff in the professional literature after 1980. Based on what was published in the 1970s, it was an interesting technique but did not come up with any advantages for commercial or military adoption or much further work. I think it does show that old paradigms aren't always worth four nickels and that, truly, thinking outside the box might come up with something new and useful.

Umm... last I looked the spectrum of FM and PM was symmetrical about the carrier frequency? (Well, the lower sideband is 180 degrees out of phase with the upper, but that's true of AM as well.) Looking at a single sine wave input to an FM or phase modulator, this comes about from the Bessel function expansion of the sidetones and J-n(x)=-Jn(x)?

I know you're far more experienced in this area than I am, however, so I'll let you explain what I'm misinterpreting here!

Don't waste your money on the cheap Heil stuff. Definitely low to mid fi at
best, and cheap import parts. Go to www.bswonline.com and browse their
microphone selections. RE-20's and 27's are FAR better made, have better
audio quality, and are DJ proof. BSW has lots of various quality mics...

The semiconductor industry is one of the most bizarre there is, but it
works for them. The average life cycle for an IC, from product
introduction to last time buy is something around 3 years, and most
forecasters think it will continue to decrease to between 12 and 18
months. I know of some parts that have had life cycles of less than
12 months. Welcome to the world of consumer electronics. When
a VCR manufacturer re-lays out his circuit board every two weeks
to take advantage of the lastest/greatest/lowest cost, why do
anything different?

Digikey stocks both Lumex and Varitronix ones, at prices from $1.66 to $8
or so (depending on price, brand, etc.)

Go to www.digikey.com and search for "lumex" and "lcd" to get started.

It is true that in the hobby market that dot-matrix LCD displays have
largely displaced numeric ones. I still like the numeric ones for my
projects.

Tim.

Yes. More or less.

>I know you're far more experienced in this area than I am, however, so I'll
>let you explain what I'm misinterpreting here!

Noooo...I'm not going to. About a million subjective years ago I had to
slog through a solution and series expansion with the only "help" I got
being a suggestion to use Bessel Functions of the First Kind.

In doing so - AND thinking about it in the process - I learned quite a
bit about the math AND the modulation process. Very useful later on.
ALL learning takes place in one's own noggin...doesn't matter whether
one is in a formal class or alone being "lectured" by print on paper
through the eyeballs.

Over on the Agilent website, I would suggest downloading their free
Application Note 150-1. That is really a subtle selling thing for their
very fine spectrum analyzers but it is also a darn good treatise on
modulation and modulation spectra for all the basic types. It should
(unless altered there) include that nice little animated display of
sidebands versus modulation index. I've always admired those H-P
appnotes, valuing most as nice little tutorials on specialized subjects.

Richard Slater in the mentioned January '77 HR article was trying to
explain a combination of FM and AM. In order to get a proper "feel"
for that (in my opinion), one needs the experience of juggling those
series terms in the expanded equation form. There IS one hint and
that is the not-quite symmetry (in numeric values) of FM and PM
spectra as compared to AM spectra. True "single-sideband" has a
possibility only on true symmetry. FM and PM spectra, by
themselves, don't have that symmetry in the expanded form. I'm
not going to discuss that one since it should be apparent.

If you want some source code on calculating the numeric values of Bessel Functions of the First Kind, I'll be happy to post it here under some thread. It's short and not complicated and a #$%^!!! faster than slugging through 5-place tables with slide rule and/or four-function mechanical calculator. Been there, done too much of that. Computers aren't just for chat rooms, are very nice for numeric calculations of the large kind. :-)

Source record: 31615

I've heard a few hams on the HF bands using homebrew microphones and I thot they sounded great.
I understand most are made from a Radio Shack (or other source) Electet mic element, which is inexpensive.

I've searched the net looking for detailed plans on building a mic, but have only found a few pictures of finished mics. There was an article in QST showing several mics a guy built. I have a couple ARRL hand books, but none have info on homebrew mics.

What I need is detailed plans and not the pictures of finished mics. How do I mount the cartridge? How are the components wired? I have the mic cartridge and plug for my Icom rig, but still need a mic cord a few feet in length. How many conductors should the mic cable have? I saw somewhere the needed voltage is obtained from the rig, but a resistor may be needed. A capacitor or two is also needed and possibly a mic pre amp??

Perhaps someone in this newsgroup has built a mic and can give some help.

Thanks and 73

Roln

I have used most of AD's DDS chips. While their data sheets might be
overwhelming, they are always correct-- so far. If you are having a problem
it is generally because of a missed detail.

Glad you found the problem.

idea had any merit it would be a popular mode by now. >>

Bruce-

It has been about 35 years since I had a class in school where SSB-FM was discussed. I recall that if you derive the equations for both AM and FM SSB, they are identical for practical purposes if the FM signal has low deviation (low modulation index?).

Looking at Two Meter FM, the deviation typically peaks at about 5 KHz. If you listen to your local repeater with an SSB rig such as the IC-706, it will be obvious that it isn't a clean signal! However, a 3 KHz deviation FM signal on HF (below 29 MHz) will sound much cleaner when tuned as SSB, and you may not notice it isn't AM-SSB.

With this in mind, consider that AM-SSB and FM-SSB might just be two ways to generate an SSB signal, assuming you use a filter to eliminate the carrier and other sideband.

By the way, an IC-706, especially one with the TCXO, often has a more accurate frequency read-out than a typical Two Meter rig. Therefore you can use it to check a repeater's frequency by tuning it as if it were an SSB station while someone is speaking. It is easy enough to check the IC-706 against WWV on HF.

The amplitudes of the sideband components are symmetrical (at least for modulation by a single sine wave), but the phases aren't. The phases of all the upper sideband components are in phase with the carrier; in the lower sideband, the odd order components (and only the odd order ones) are reversed in phase. With multitone modulation, things get a whole lot more complex. Unlike AM, FM is nonlinear, so there are sideband components from each tone, plus components from their sum, difference, and harmonics. The inability to use superposition makes analysis of frequency modulation with complex waveforms a great deal more difficult than AM.

Note also that unlike AM, whatever fraction of the carrier that's left when transmitting FM also contains part of the modulation information. Of course, at certain modulation indices with pure sine wave modulation, the carrier goes to zero, meaning that all the modulation information is in the sidebands. But this happens only under specific modulation conditions, so you'd certainly have an information-carrying carrier component present when modulating with a voice, for example.

Egad, yes. Every year, the new TVs had an altogether new tube lineup. The tubes were generally the same old stuff, but in new envelopes with different pinouts, or different combinations in one envelope. All the service shops had to buy and stock a bunch of new tubes each year. That sort of greedy planned obsolescence was one of several reasons TV manufacturing rapidly died out in the U.S.

I certainly didn't realize that until you pointed it out; I was generalzing from the narrowband FM situation where only the first sideband components are necessarily maintained and incorrectly assuming the same phase differences applied to the general case.

However...

Say you start with a baseband FM signal. Let's call the two sides of its Fourier transform L and R for the 'left' and 'right' halves. Now we mix up to the desired carrier frequency. At -f_c we have L at even greater negative frequencies and R at smaller negative frequencies. Ditto at f_c. If we now apply a low pass filter to select the lower sideband, we end up with R and L --> No information has been lost! (Likewise, with a high pass filter you have L and R left --> Same deal.)

Fundamentally mixing ANY signal followed by SSB filtering shouldn't lose information. Yes, in practice we'll be talking about VSB instead of SSB, but I still think we're OK.

Speaking of narrowband FM (NBFM)... and at the risk of splitting this topic... I had a discussion today with someone over the ability to use an envelope detector to recover narrowband FM signals. The output of the envelope detector is approximately 1+0.5*cos^2(2*pi*f*t), where f was the original modulating signal. The '1' will be killed by a capacitor, but that leaves the cosine squared term... which seems impossible to easily change back into cosine, since sqrt(x^2)=abs(x) and therefore it would appear that we've irreversably lost information. Comments?

You're probably thinking of AM vs. narrow band FM. Although the equations look very similar on paper and the MAGNITUDE spectrum is identical, the phase spectrum is different in that -- in the phasor domain -- AM always sits at 0 degrees and just grows and shrinks with modulation (overmodulation pushes it over to 180 degrees, BTW). NBFM, on the other hand, still has the carrier at 0 degrees but grows and shrinks along the imaginary axis. Hence the angle of the phasor is small but time-varying (which implies that the instantaneous frequency is varying as well -- but of course you already knew that since we called this whole mess 'frequency modulation'). The angle is about 15 degrees for a modulation index of 0.3 (what my notes claim as a good cutoff for NBFM) and about 5 degrees at 0.1.

See the message I posted earlier tonight for a discussion of whether or not you can recover NBFM with an envelope detector as of course one often does with AM (the difficulty is due to that phasor's wiggling...). I think not, but there's plenty I don't have a clue about... yet!

What's the modulation index on two meters anyway?

---Joel Kolstad

I'm afraid you lost me with the "baseband" FM signal. Would you provide a carrier frequency, modulation frequency, and deviation or modulation index as an example?

The lower and upper sidebands of an FM signal do contain the same information when the modulation is a single sine wave, even though the sidebands aren't identical. But when you modulate with a complex waveform, you might find that some of the information which is adding in one sideband is subtracting in the other, and you might not be able to recover the modulating waveform from only one or the other -- sort of like you can't get two separate stereo channels from just the sum signal. I don't know if that's true, but it wouldn't surprise me. And, as I pointed out in another posting, the entire modulation information isn't even contained in *both* sidebands except under very special conditions -- some is in the carrier. Another question, of course, is whether you can get close enough to be useful. Perhaps with NBFM, at least, you could.

Cos^2(x) = abs(cos(x)) = 1/2 * (1 + cos(2x)). As you've noted, the DC term can be blocked with a capacitor, so you'd end up with a cosine wave at twice the frequency.

But I've never heard of trying to detect NBFM directly with an envelope detector like you'd detect AM. The trick we used in ye olden tymes was called "slope detection". You tuned the signal so it was on the edge of the IF filter. The filter slope converted the FM to AM, which was then detected with the normal AM envelope detector. If you tuned directly to the carrier frequency, you didn't hear any modulation to speak of.

The ITU-R emission designations are quite outdated and many modern
emissions use din commercial and military systems would be designated
as XXX. In each case the X means "none above" in the corresponding
column.

Anyway, why should the amateur radio regulations contain these ITU-R
designations ? Here in Finland, ITU-R emission designations were
removed from amateur radio regulations and exam in 1997 and only band
specific power and bandwidth limits are used. I haven't heard of any
problems due to this decision.

Ramsey sells a 2M crystal-controlled (single channel) FM transmitter for
about $70. No receiver. I'd be extremely reluctant to recommend this to a
newbie because they'd need a separate receiver too.

Ten-Tec's 1220 (2M) and 1260 (6M) kits are nice radios, but are $200
and way way more than what you asked for. They are full-fledged
digital PLL radios. They're good values, but not what you asked for.

I think you'd be better off getting some older crystal-controlled
transceivers (assuming you can find any!) and teaching newbies how
to put a crystal in for the local repeater and align them.

Tim.

Speaking of AM modulation,, we all know that the carrier amplitude
does not change with modulation. Or does it?

Here is a question that has plagued many for years:
If you have a plate modulated transmitter, the plate voltage will
swing down to zero and up to two times the plate voltage with 100%
modulation. At 100% negative modulation the plate voltage is cutoff
for the instant of the modulation negative peak.

How is the carrier still transmitted during the time there is zero
plate voltage?

If we lower the modulation frequency to say 1 cps or even lower, 1
cycle per minute, then wouldn't the transmitter final be completely
off for half that time and unable to produce any carrier output??

Question is, at what point does the carrier start to be effected?

Roln:

The last electret element I bought from Radio Shack had the wiring diagram for it printed on the back of the blister pack card.

For your radio, look in the owner's manual. It should show the microphone connector pinouts. Most modern HF rigs have DC available (8 volts or so) on one of the pins.

The mic cable will need enough wires for:

1. ground (may use the shield on #2)
2. audio (shielded)
3. PTT (push to talk)
4. DC voltage to operate the electret element

Radio Shack may also carry the 8 pin microphone connector that is compatible with yaecomwood radios.

www.rfparts.com

buy a motorola or similar RF module. aka a "CATV Brick" or "CATV AMP".

cost 60-90$ US.

usually runs off 12 or 24 volts, and get the app note/manufaturers data from RF parts

make sure you have a good RF wattmeter and adjust the source before the amplifier to avoid overdrive. overdrive is BAD. It will need a heatsink!

if your really transmitting with it, put a filter on the output as many of those modules have bandwith from 0 to 550 mhz or so. The law says any harmonics and spurs you generate must be about 40 Db down from your output

time spent building anything else without the proper equipment,is priceless, and judging from the language in your post, you dont have the skills/milliwatt meter to do it.

Dont expect this fowarded via email.

You have to be careful in what you call the "carrier". As soon as you start modulating the "carrier", you have more than one frequency component. At that time, only the component at the frequency of the original unmodulated signal is called the "carrier". So you have a modulated RF signal, part of which is the "carrier", and part of which is sidebands.

General frequency domain analysis makes the assumption that each frequency component has existed forever and will exist forever. So under conditions of modulation with a periodic signal, you have three components: A "carrier", which is not modulated, but a steady, single frequency, constant amplitude signal; and two sidebands, each of which is a frequency shifted (and, for the LSB, reversed) replica of the modulating waveform.

You can take each of these waveforms, add them together in the time domain, and get the familiar modulated envelope.

So, the short answer is that the carrier, which is a frequency domain concept, is there even if you're modulating at 0.001 Hz. But to observe it, you've got to watch for much longer than 1000 seconds. You simply can't do a meaningful spectrum analysis of a signal in a time that's not a lot longer than the modulation period.

> and way way more than what you asked for. They are full-fledged
> digital PLL radios. They're good values, but not what you asked for.

I'd hedge a little on that "good values" statement. At least for 2 meters, already built, name brand, far more capable radios cost less than the Ten-Tec kit. Now perhaps it's worth some premium to come from Seiverville rather than Tokyo, but you do pay for it.

And Brian, if I were you, I'd think hard about what your motivation is. VHF radios are a lot more difficult to build than HF radios. If your interest is homebrewing, then go for it. But if you are looking for something that you can operate and save a few bucks, then homebrewing something isn't the way to go for VHF.

On VHF, layout is very important. Tiny differences in how things are put together can have a huge impact on performance. The Ramsey receiver is a good case. The thing is so wide and unstable that it's virtually useless on the ham bands, unless you are out in the middle of nowhere. If you choose to build something from a schematic, prepare yourself for a lot of tinkering to get it right. Likely your construction time will be measured in years, rather than months, unless you are very experienced at this sort of thing.

The Ten-Tec is a good one to look at for a kit. I'm sure, knowing Ten-Tec's reputation, that it works well. But compare the price and feature list to, say, an Icom 2100. You get a fifth the power, a tenth the channels, and half the receive coverage, for a 25% higher price. Plus, you miss a pile of the frills that adorn the typical rice box these days.

All that having been said, there is no thrill quite like operating a radio you built yourself. If that's what you are after, then by all means, go for it. Just recognize up front that, expecially at VHF, there is a price, and it's pretty significant.

<< You're probably thinking of AM vs. narrow band FM. Although the equations look very similar on paper and the MAGNITUDE spectrum is identical, the phase spectrum is different >>

Joel-

Perhaps that is what I'm remembering. Now, if you use a filter to eliminate the other sideband, the higher frequency components and the carrier, don't you have a nearly identical remainder?

<< See the message I posted earlier tonight for a discussion of whether or not you can recover NBFM with an envelope detector >>

Somehow I missed that one. It seems that AOL does not post messages in the order in which they were originated!

I think we are in agreement that you can't recover FM modulation with just an envelope detector, but there is another approach. Again, you need a filter, but maybe one that is not as sharp as above. If you tune the radio so the carrier is just outside the passband, an amplitude variation will occur as the signal slides up and down the shoulder of the filter. The result is a pseudo AM signal that is detected by the envelope detector. I recall that this approach is called "slope detection".

I get lots of compliments on my audio, using a "computer" head set that uses an electret mic. You can spend up to $15 at R.S. and get a nice one. At the local big box electronics store, I saw sets with leather like ear pads, or foam ear pads. I borowed a Labtec from a friend and tried it out and was happy with that as well.

I find it much easier than using a desk mic. Since your mouth is always the same distance from the microphone you can have better audio and not have to play with the Mic Gain on your radio very often.

You can see the one that I use on QRZ or at
http://user.mc.net/~jdewey/Ham_radio/ka9car.jpg

One of the Ham Radio Magazines ran an article in the last couple of years, showing how to use plastic pipe fittings to mount the element and make a desk stand.

I have used my "desk mount" Sound Blaster microphone, You can get them at ham fests or flea markets for $3.00 or buy a replacement at your local big box electronix store for about $10.00

Here is a schematic of how I added the proper voltage to my radio.

http://user.mc.net/~jdewey/KACHINA/Electret_mic_bias.jpg

Those PIN NUMBERS apply ONLY to a Kachina 505DSP.

I used the same head set in My Alinco (DX-77T), There was already a power supply on the board all I had to do was install a jumper to liven up the mic. Most ICOM radios are powered.

Good luck.

At that point I don't think you could tell the difference since there's no longer any local phase reference (i.e., the carrier) to compare with. I suppose this is why your SSB-AM rig is able to (somewhat) receive low frequency (and thereby presumably narrowband) FM broadcasts; this is what you were saying in your last post, correct?

> I think we are in agreement that you can't recover FM modulation with
> just an envelope detector

Yes, at least you can't recover a signal that directly corresponds to what you transmitted. It does appear that you can recover the signal's square, however, so this approach might be useful for, e.g., remote command transmissions. (But probably just for the novelty of having said you did it... since it's probably not much harder to build the slope detector you describe!)

Along the same line consider that the envelope of an SSB signal has no
direct relationship to the original modulation the way that an AM
signal does.

This is why you can not use RF derived ALC to control the audio stage
of an SSB transmitter the way you can with an AM transmitter.
Or audio clipping that works on AM but does not work the same on SSB.

Transmit a square wave on an AM transmitter and you see a square wave
in the AM envelope. Do the same with an SSB transmitter and you only
see sharp spikes in the envelope.

>manufacturing rapidly died out in the U.S.

Not quite that, Roy. Off-shore production could do it cheaper.

29 years ago an in-house RCA publication announced that all
black-and-white RCA television sets would be made off-shore
while the Indianapolis, Indiana, complex continued with color
TV receivers. I was working for RCA in Van Nuys, CA, at the
time and was considering buying one through the company
store to save me money.

Back then the TV sets were still using tubes, still had the
rotating turret tuners for the low band, few manufacturers
offered remote controls. "Greedy planned obsolescence?"
No, just a lot of competition. Competition drove pricing and
low pricing required significant design changes like all series-
strung tube filaments to get rid of the power transformer.

The old RCA Indianapolis TV works is still operating, still uses
the RCA logo even though it is now owned by Thomson-CSF.
[or did it change hands again?]

So, three decades later where are all the other U.S. TV set
factories? Check out Circuit City, Best Buy, Wal-Mart,
K-Mart, Lowes, etc., and see where they are made NOW.
Back in 1958 Radio and Television News magazine had a
special edition on TV and included a representative listing of
color TV sets, all American made, all the cheap ones costing
about $500 in 1958 dollars. Nowadays an equivalent size
display color TV, plus remote control, plus PLL electronic
tuning for VHF through UHF channels, plus built-in captioning,
plus full sweep AFC, plus on-screen setting, plus a clock,
costs less than $300 retail in 2003 dollars...those are all
off-shore built, says so on their back panels.

For that matter, what happened to all those famous U. S.
makers of tube-type ham radios? Like Hallicrafters, National
Radio, RME, Collins Radio (Collins still alive but left the ham

market quite some time ago), Hammarlund.

In February, 1953, I did my first QSY on HF with a BC-339 that ran a
pair of 833s in the final. 833 is not your run-of-the-mill receiver set
tube. :-)

About the same time a group of the guys at Army station ADA were
into an argument about "how many vacuum tube types" there were
then. (I guess it was something to do) Several scarfed up catalogs
and things, even got the station OIC interested. I forget the exact
number but it was like 3500 nomenclature types of all kinds, receiving,
transmitting, power control, photoelectric eyes, whatever.

By 1960 there were the 12 V filament versions of basic 6 V tubes
and the other "weird" filament voltages for series-stringing to
reduce the cost of a transformer in a TV set. Ruggedized versions
of basic lower-power tubes for mobile and airborne were out with
5000 and 6000 series numbers. Loctals were disappearing as
were the "acorn" types for VHF-UHF. Big changes everywhere,
not just on TV sets, to meet both competition and new environments
and frequencies. Sylvania's tube spec book had small loose-leaf
pages, at least two update sets per year...:-)

By 1980 the number of available-on-the-market semiconductors were
at least two orders of magnitude greater than that old 1953 group
compilation of tubes done at ADA...maybe three orders of magnitude.
All kinds of ICs for many, many purposes and universal applications
like the all-purpose Opamp (bless you, Bob Widlar, wherever you are).

By 1990 there was already a trend of "downsizing" semiconductor
product lines. National Semi and Motorola data books were no longer

expanding beyond their one-foot shelf width for most volumes. There was COMPETITION on the world market for all kinds of electronics and it was fierce and hot, not just in PCs+peripherals but all kinds of electronic things and products. The number of available semi products had expanded beyond reasonable capitalistic bounds and the market overall just couldn't sustain all of them.

>Ahhhhh, the good old days.

Bill, I respectfully give you a pthbtbtbt on that. :-)

I DON'T want them back now that the whole electronics world is swimming in a sea of wonderful parts plethora! Sure, it's getting to be a chore on selecting a precise IC or transistor...because there's SO MANY to choose from. In 1956 one was lucky to get a transistor (affordable) that would work beyond audio frequencies.

Just got a Mouser paper catalog a couple days ago. It's a full inch and a half thick with very thin paper contents. The Digi-Key industrial catalog on paper is about that size, maybe larger. HUGE inventories! Pages of semiconductor components that don't seem to stop. All kinds of semis, all kinds of other components...TTL expanded to many families, CMOS functional work-alikes to TTL numbers for zilch power drain...voltage regulators, band-gap voltage references more precise than zeners, all kinds of FETs capable of POWER handling, RF transistors capable of working at 1.2 GHz, small signal FETs approaching that. Huge selection of Microchip microcontrollers that anyone can use and program with free software, displays that knock the eyes out, LEDs of many colors.

Yes, the traditional "radio" parts aren't there anymore, not in the Allied or Newark catalogs either. "Plate transformers" are hard to get and only specialty places still sell variable capacitors for "tuning." Even vacuum tube sockets are getting hard to get. The electronics world get very big everywhere and it got much lower in voltage and much bigger in functions for all kinds of purposes. Times change.

These are times of paradise for designers! I wouldn't have it any other way... :-)

Roger that! :-)

The first time I had to really calibrate an FM deviation indicator, I had
to use the "carrier null" technique with a narrow-bandpass detector
(actually a spectrum analyzer). Say WHAT?!? I thought. The
carrier amplitude goes to ZERO?!? Impossible, I thought, "everyone
knows" that an FM carrier "swings from side to side." :-)

Not long after that I got deep into modulation theory and discovered
the how and why of that. Mind-blowing at the time, but it explained
what was going on.

It's a situation where one has to look at either frequency domain or
time domain very hard in order to realize how the two are related.

>Speaking of AM modulation,, we all know that the carrier amplitude >does not change with modulation. Or does it?

Yes and no.

It's a situation of subjective understanding of the basic modulation formulas which define the amplitude of an "RF" waveform as a function of TIME [usually denoted as RF voltage "e (t)" meaning the voltage at any given point in time].

With a REPETITIVE modulation waveform of a single, pure audio sinewave, AND the modulation percentage LESS than 100%, the carrier frequency amplitude does indeed remain the same. I put some words into all-caps for emphasis...those are required definitions for proof of both the math AND a bench test set-up using a very narrow bandwidth selective detector.

One example witnessed (outside of formal schooling labs) used an audio tone of 10 KHz for amplitude modulation of a 1.5 MHz RF stable continuous wave carrier. With a 100 Hz (approximate) bandwidth of the detector (multiple-down-conversion receiver), the carrier frequency amplitude remained constant despite the modulation percentage changed over 10 to 90 percent. Retuning the detector to 1.49 or 1.51 MHz center frequency, the amplitude of the sidebands varied in direct proportion to the modulation percentage.

That setup was right according to theory for a REPETITIVE modulation signal as measured in the FREQUENCY domain.

But, but, but...according to a high-Z scope probe of the modulated RF, the amplitude was varying! Why? The oscilloscope was just linearly combining ALL the RF products, the carrier and the two sidebands. The scope "saw" everything on a broadband basis and the display to humans was the very SAME RF but in the TIME domain.

But...all the above is for a REPETITVE modulation signal condition. That's relatively easy to determine mathematically since all that is or has to be manipulated are the carrier frequency and modulation frequency and their relative amplitudes. What can get truly hairy is when the modulation signal is NOT repretitive...such as voice or music.

I don't blame you for being puzzled...I used to be so for many
years long ago, too. :-)

Most new commercial AM transmitters of today combine the
"modulator" with the power amplifier supply voltage, getting rid of
the old (sometimes mammoth) AF power amplifier in series with
the tube plate supply. Yes, in the TIME domain, the RF power
output does indeed vary at any point in time according to the
modulation. [that still follows the general math formula, "e(t)"]

You can take the modulation frequency and run it as low as
possible. With AM there is no change in total RF amplitude
over frequency (with FM and PM there is). If you've got an
instantaneous time window power meter you can measure it
directly (but ain't no such animal quite yet).

If you set up a FREQUENCY domain test as first described, you
will, indeed, measure NO carrier amplitude change with a very
narrow bandwidth selective detector at any modulation percentage
less than 100% using a REPETITIVE modulation signal.

Actual modulation isn't "repetitive" in the sense that a signal
generator single audio tone is repetitive. What is a truly TERRIBLY
COMPLEX task is both mathematical and practical PROOF of
RF spectral components (frequency domain) versus RF time
domain amplitudes when the modulation is not repetitive. Please
don't go there unless you are a math genius...I wasn't and tried,
got sent to a B. Ford Clinic for a long term. :-)

In a receiver's conventional AM detector, the recovered audio is
a combination of: (1). The diode, already non-linear, is a mixer
that combines carrier and sidebands producing an output that is
the difference of all of them; (2). The diode recovers the time
domain amplitude of the RF, runs it through a low-pass filter to
leave only the audio modulation...and also allows averaging of the
RF signal amplitude over a longer time. Both (1) and (2) are
technically correct.

With a pure SSB signal there is a constant RF amplitude with a
constant-amplitude repetitive modulation signal, exactly as it
would be if the RF output was from a Class C stage. Single

frequency if the modulation signal is a pure audio tone. With a non-repetitive modulation the total RF power output varies with the modulation amplitude. The common SSB demodulator ("product detector") is really a MIXER combining the SSB input with a constant, LOCAL RF carrier ("BFO") with the difference product output...which recovers the original modulation signal.

>Question is, at what point does the carrier start to be effected?

Beyond 100% modulation. The most extreme is a common radar pulse, very short in time duration, very long (relative) in repetition time. There's a formula long derived for the amplitude of the spectra of that, commonly referred to as "Sine x over x" when spoken. That sets the receiver bandwidth needed to recover a target return.

I've gotten waist-deep into "matched filter" signals, such as using a 1 MHz bandwidth filter to recover 1 microSecond RF pulses. (bandwidth is equivalent to the inverse of on-time of signal, hence the term "matched" for the filter) Most folks, me included, were utterly amazed at the filtered RF output envelope when a detector was tuned off to one side by 1, 2, or 3 MHz. Not at all intuitive. The math got a bit hairy on that and I just accepted the late Jack Breckman's explanation (of RCA Camden) since it worked on the bench as predicted.

It's all a matter of how the observer is observing RF things, time domain versus frequency domain...and whether the modulation is repetitive single frequency or multiple, non-repetitive. The math for a repetitive modulation signal works out as the rule for practical hardware that has to handle non-repetitive, multi-frequency modulation signals.

When combining two basic modulation forms, things get so hairy its got fur all over. So, like someone explain how an ordinary computer modem can send 56 Kilobits per second over a 3 KHz bandwidth circuit? :-)

Okay, I won't argue the ITU-R thing since I haven't had the ability
(by working for a subscribing corporation) to access them. I was
going by the "Red Book" information from the U. S. National
Telecommunications and Information Agency (NTIA). Over here
the NTIA regulates government radio use while the U. S. Federal
Communications Commission regulates civil radio use. The
method of specifying modulation type, bandwidth, etc., are all
explained in there and the FCC follows the same nomenclature.

>Anyway, why should the amateur radio regulations contain these ITU-R

That's a whole other area that, for amateur radio use, can be and has
been argued in rec.radio.amateur.policy.

As far as I'm concerned, and no one has ever proved otherwise,
electrons, fields, and waves all follow the Laws of physics...and they
don't give a @#$%!! about human laws. :-)

Hmm... and to think it wasn't until the '80s or thereabouts that cars started to become noticeably non-user-serviceable... (Well, I suppose you guys just checked the pins of the tube bases to see where the voltage stopped? Not too bad...)

One of the things people should keep in mind is that -- especially in the digital world -- one device can replaces tons of older ones. If you need fast digital logic, use a CPLD or FPGA. For slower stuff, nothing can beat the versatility of a microcontroller, and these days they're dirt cheap with tons of features. Analog electronics is certainly still struggling in that programmable analog devices based on, e.g., switched capacitor architectures tend to noticeably limit performance in a manner that makes their usage nichey (i.e., if you can afford the ADC and DAC anyway, a lot of programmable analog chips perform no better than an ADC, DSP, and a DAC), but at the same time Analog Devices, Linear Tech., etc. keep cranking out some very impressive op-amps, regulators, etc. (Just off-hand, the LTC1799 is a pretty nice chip that's already found its way into some amateur radio equipment!)

I'm personally quite interested in bridging the digital and analog worlds of radio design, applying each where it makes the most sense.

"It" only exists in the frequency domain. Talking about the carrier in the time domain makes no more sense than talking about the sidebands in the time domain, or the envelope in the frequency domain.

Yep, we have reached the logical heights of electronic absurdity -
parts are discontinued so rapidly that I am seeing big television
sets, 12 months old, with discontinued chips in them (Philips seem to
be the worse in this department). Added to this the price of new
domestic equipment (TV,VCR etc) is so cheap that it is indeed "throw
away". Pity I am trying to still make a living fixing these things.

If you get more than the statutory 12 months life from it, then thats
a bonus - or, think like an MBA and realise it has cost you $5 a week
to run.....

The generation gap widens ever more, and, like the dinosaurs, we who
remember spares in stock NOW are a dying breed....

You can't use ENVELOPE detection on SSB the same way it is
done on conventional AM.

But, you CAN use RF-derived feedback - if mixed with a steady
carrier to recover the modulation content - to do that very well.

>Or audio clipping that works on AM but does not work the same on SSB.

? Wrongly-done audio clipping on AM is just as bad as on SSB.

RF clipping circuits are quite another thing from audio.

>Transmit a square wave on an AM transmitter and you see a square wave
>in the AM envelope. Do the same with an SSB transmitter and you only
>see sharp spikes in the envelope.

That depends on the frequency of this square wave. That also depends
on what is being used to view the RF envelope. A 50 MHz scope will
show the RF envelope of any HF rig.

Put an electronic keyer on the SSB transmitter and transmit only dots
at a high speed setting. The SSB envelope will show the dots as
dots.

Conversely, if you put a high-purity sinewave audio into a SSB xmtr,
a spectrum analyzer display will show only a single frequency signal.

No one can interchange frequency and time domains directly and
get an explanation. Envelope viewing is time domain. Spectral
analysis is frequency domain.

You might be thinking more than 29 years. In 1968 I worked for RCA Service. The CTC 25 was big and the CTC 40 was making its appearance; most makers offered remote control, though few people bought it back then; RCA was using mostly wafer tuners in the color sets by then.

But yeah, pricing was already on the decline along with features we thought meant quality. I remember they had one large-screen color TV (25"?) in a plastic cabinet; they put a handle on the top of it so that warranty on the set was strictly carry-in, to save warranty service call costs. GE was hitting with PortaColor, series filament sets with the weirdest tube numbers ever seen. Replacing all the tubes in the set at retail price cost nearly as much as the set cost originally.

Hi Len,

I understand all of the points that you have made and agree that looking at a spectrum analyzer with a modulated signal, less than 100% modulation, shows a constant carrier. I also agree that looking at the time domain with a scope shows the composite of the carrier and side bands.
I understand that AM modulation and demodulation is a mixing process that takes place.

My question of "at what point does the carrier start to be effected" I was referring to low frequency modulation. Meaning when would you start to notice the carrier change.

I don't know how you would observe the carrier in the frequency domain with very low frequency modulation as the side bands would be so close to the carrier.

In my scenario of plate modulating a transmitter with a very low modulation frequency (sine or square wave), on the negative part of the modulation cycle the plate voltage will be zero for a significant amount of time of the carrier frequency. The modulation frequency could be 1 cycle per day if we chose. In that case the plate voltage would be zero for 1/2 a day (square wave modulation) and twice the DC plate voltage for the other half day. During the time the plate voltage is zero there would be no RF out of the transmitter as there would be no plate voltage.

This is where I get into trouble visualizing the "carrier staying constant with modulation". As the above scenario, there would be zero output so zero carrier for 1/2 a day. The other 1/2 day the plate voltage would be twice so we could say that the carrier power during that time would be twice what it would be with no modulation and that the average carrier power would be constant. (averaged over the entire day).

But we know that the extra power supplied by the modulator appears in the side bands and not the carrier.

What is happening?

Message-ID: <vph4u9aail1u1f@corp.supernews.com>
Source record: 31560

Let me elaborate a little. Maybe the following example will help.

Suppose you've 100% modulated a 1 MHz carrier with a 0.1 Hz sine wave. Our knowledge of frequency domain analysis tells us the spectrum will be a 1 MHz "carrier", with two sidebands, one at 1,000,000.1 Hz and the other at 999,999,999.9 Hz. At 100% modulation, the power amplitude of each sideband will be 1/4 the amplitude of the carrier; the voltage amplitude of each will be 1/2 the amplitude of the carrier.

Now, imagine that you can draw three sine waves on a long piece of paper. They would have the frequencies and amplitudes of the three spectral components above. These are the time domain representations of the three frequency domain components. (In that sense, you *can* speak of a carrier or a sideband in the time domain -- so I was perhaps unduly dogmatic about that point.) But here's the important thing to keep in mind -- all three of these components have constant amplitudes. They extend from the beginning of time to the end of time, and don't start, stop, or change at any time. That's what those spectral lines mean, and what we get when we transform them back to the time domain.

At each instant of time, look at the values of all three components and add them. At some times, you'll find that the two sideband sine waves are both at their maxima at the same time that the carrier sine wave is at its maximum. At those times, the sum of the three will be twice the value of the carrier wave alone. At some other times, both sidebands are hitting their maxima just when the carrier is at its minimum value. At those instants, the sum will be zero. After you plot enough points, you'll find you've reconstructed the time waveform of the modulated signal. You'll also find you need at least ten seconds of these three waveforms to create one full cycle -- repetition -- of the modulated wave. During that ten second period, the carrier sine wave doesn't change amplitude, nor do the sideband sine waves change amplitude. Only the time waveform, which is not the carrier or the sidebands, but always the sum of the three, changes. When we speak of a carrier wave, we mean that sine wave of constant amplitude that never changes -- in other words, a single component in the frequency domain.

Agreed.

>
>>Or audio clipping that works on AM but does not work the same on SSB.
>
> ? Wrongly-done audio clipping on AM is just as bad as on SSB.
>
> RF clipping circuits are quite another thing from audio.

In SSB RF clipping, the signal being peak limited is the same as that
being transmitted.
If you do audio clipping on an SSB transmitter you can not limit the
peak output as you can in AM or in RF clipping of SSB, because the
output of the SSB transmitter has no direct relationship to the audio
in.

>
>>Transmit a square wave on an AM transmitter and you see a square wave

> show the RF envelope of any HF rig.

With a 1000hz audio square wave into an SSB transmitter you will not
see a square wave envelope as you would from an AM transmitter. You

will see sharp spikes.
My point is that what you get out of an SSB transmitter is not
directly representative of what you put in, as it is in AM.
Even though the modulation process in the SSB transmitter starts out
the same as it does in the AM transmitter. Much phase modulation takes
place in the SSB process.

>
> Put an electronic keyer on the SSB transmitter and transmit only dots
> at a high speed setting. The SSB envelope will show the dots as
> dots.

Same as a CW transmitter.

>
> Conversely, if you put a high-purity sinewave audio into a SSB xmtr,
> a spectrum analyzer display will show only a single frequency signal.

Put two pure equal amplitude audio tones into the SSB transmitter and
the envelope out at first glance looks like a 100% modulated AM
transmitter envelope that is modulated by a single tone. But a closer
look will reveal that the envelope is not a pure sine wave. The
envelope is folded over so as to produce a sharper crossover.

If this signal is looked at or listened to on an envelope detector the
detector will produce high 2nd harmonic distortion. (that's another
story)

Look at the signal on a spectrum analyzer and it will show 2 carriers
seperated by the seperation of the two tone frequencies.

That's good to know. Essentially, my situation is that I can afford a
very basic HT; 2M is not so much a big deal as 6M, which would seem to
be somewhat easier. Basically I can't afford a triband radio, so I want
to build one for 6M. 2M would be gravy, but apparently it's not worth
the trouble to try to build. I won't worry about it -- I'll just go
shopping.

Very good to know. In that case, I won't bother until I know what I'm
doing. At least not on 2M.

Well, I got my ticket for the tech. I didn't know going in just how complex it would be, expecially given how simple something like a Pixie is.

Thanks for the commentary. Sadly, it looks like I'll be stuck on 2M for the forseeable future, at least until I get my General ticket. Whenever that is.

Okay, so how does anyone justify spending $40 to $60 an hour
repair charges for an $89 DVD-VHS dual-deck unit purchaseable
at the Fry's Electronics chain?

Nearly all consumer electronics things work just fine right out of
the packing box and stay that way for years.

>what we get when we transform them back to the time domain.

It is quite easy to visualise this using a spreadsheet program.
However, it would be easier to use a much higher modulation frequency
compared to the carrier frequency. Assuming a carrier frequency of
1000 Hz and a modulating frequency of 100 Hz, so the sidebands would
be at 900 and 1100 Hz.

In column A put the time t and for each line increment the value by
0.0001 s or 0.00005 s.

In column B calculate 0.5*sin(2*pi*900*t).
In column C calculate 1.0*sin(2*pi*1000*t).
In column D calculate 0.5*sin(2*pi*1100*t).
In column E calculate the sum of columns B, C and D.

Duplicate these lines 500 to 1000 times and draw a graph, with column
A or time as the X-axis and display columns B, C, D and E as separate
graphs on the Y-axis.

Hams have always used anything available. 25 years ago was 1977. By that time the vast majority of receivers were designed for 8-ohm headphones as most are today. Hi-Z crystal phones haven't been in general use for a long time.

Depending on where you are, a 2M HT can be pretty handy. Actually, single
band mobiles are probably cheaper than HT's. If you have a number of
repeaters nearby, then the HT may be more flexible. If you need a little
power to reach out then the mobile might be a better choice. (Although if
you're not going to mount the mobile in a car then the power supply does
almost double the cost).

> Very good to know. In that case, I won't bother until I know what I'm
> doing. At least not on 2M.

Actually, you can get on 6 meter CW pretty simply with homebrew stuff, but
recognize that QSOs are going to be few and far between. 6 meters is only
open occasionally, and even less frequently to low power. In most parts of
the country there is relatively little local 6 meter operation, so your QSOs
are going to be largely limited to band openings, unless you are in a major
metro area.

> Well, I got my ticket for the tech. I didn't know going in just how
> complex it would be, expecially given how simple something like a Pixie
> is.

Yeah, well, as I said. You can build a Pixie-like thing for 6 meters, in
fact, I did such a thing relatively recently to try to get a friend upgraded
(no such luck, he seems to have a block for the code). But the problem is
that 6 is open so rarely, and 6 meter CW operation is pretty scarce. SSB or
FM add a whole pile of complexity, although SSB receive on 6 meters could
be pretty simple since the band is rarely crowded.

BUT, to get the frequency stability you either need to go with crystal
control or a DDS. Now crystal control may not be as much of a disadvantage
on 6 as it is on most other bands, since probably 90% of the operation is on

50.125. But it will be frustrating to be unable to move away from the QRM on that one day a year that the band is open and you happen to be there! DDS can quickly put the cost up there.

Now, if you have a buddy nearby and you want to get your code speed up for the general, I have a circuit you can build for around $25 that will get you on the air. But it's CW, fixed frequency, and low power. Given the infrequency of 6 meter openings that are friendly to low power, that means the QSOs are going to be limited to a nearby station.

I should add, I don't mean to imply that 6 meters is a big power band. Indeed, the noise and absorption are both low o 6, which makes power less of an issue for "traditional" openings. But on 6, traditional openings are rare, so you look for other modes more frequently. There are basically 4 kinds of openings on 6 that are fairly common.
- F - very rare, friendly to low power
- Es - somewhat less rare, very unpredictable, friendly to low power, although you will often be competing with high power stations
- Aroura - getting unusual with the sunspots going down, high power
- HSMS - common, predictable, high power

If you want a QSO on 6 almost every day, HSMS is a good bet. *BUT*, you need a good antenna, preferably with an az-el mount, lots of power (a few hundred watts, anyway), and a computer.

Hunting QSOs on 6 is a lot of fun, but if it's your only outlet, it could get pretty frustrating because they are pretty rare, and getting tougher as the sunspots decline. With low power and fixed frequency it will be even tougher.

..

The high impedance phone that came with the crystal radio that I had when I was a kid in the 50's had a large stationary coil wound around an iron core. The sound was produced in a steel disc suspended over the iron core. Because the coil was stationary and its mass did not have to move, it could achieve the hi-z by adding many turns. Phones of 2K or higher can be driven directly from the plate of a vacuum tube circuit. Is that the context of your question? You could use a modern lo-z phone in such a circuit with a matching plate-to-voicecoil type transformer.

The cartridge is the microphone. The casing is really just there to protect
the cartridge, make it easier to hold, and have a place for a push to talk
switch.

While the case could affect the operation of the cartridge, I'm not sure
this is really that relevant in a microphone intended for speech. More
important, I doubt most of those "build your own microphone" articles
concern themselves with this. Someone finds a neat box or case they
can put the cartridge in, or maybe they look for something that will
work. So realistically, there isn't much to those articles, beyond
maybe giving someone some ideas for how they could do the same thing,
but differently.

Find a case or box that you find comfortable in your hand. Find a suitable
switch. Buy an electret cartridge, or pull one out of a tape recorder,
cellphone, cheap telephone, or cordless phone (and probably other consumer
electronic goods). Drill a hole for the sound, and mount the cartridge
behind it. Use some of that silicone stuff, the proper name escapes me
at the moment, to hold the microphone in place. Drill a hole for the
switch, and if it doesn't mount on the case, you'll have to figure out
a means of mounting it behind the case. (If I was buying cheap, I think I
might try one of those pushbutton switches used in VCRs and other consumer
equipment, though I don't know their lifespan, and they might not be
the best choice in terms of mounting.). Wire it all up, someone else
detailed this in the thread. Try it out. If it doesn't sound right,
then maybe fiddle with where the mic is mounted on the case. Or find
another case. If it isn't comfortable in the long run, maybe the
switch isn't really suitable for holding down for long periods, then
try again. Unless you are spending big money on the case, the parts
are pretty disposable because they are cheap.

you can create a "floating ground" -- if you can't find a small transformer
with CT -- use a pair of resistors AND a pair of diodes -- you will also
probably find a discarded cell phone charger which fits the bill.

I may build one to play with it. Paul's documentation is awesome -- I
can well imagine how much work he put into it.

At a glance, though, there are a couple of things I would have (and may
still) do differently if/when I get around to building a VNA:

1) I don't know that I'd use DDS synthesizers for an application like
this. There's no need for serious close-in spectral purity, but you'd
certainly like to have a higher frequency-coverate limit. Also, to
achieve truly-meaningful measurements with an untuned receiver section,
suppression of harmonic content in the test signal might be more
critical than the existing design allows. (Imagine trying to
characterize a high-pass filter with an untuned receiver and DDS
harmonics coming through at -30 dBc.) The latter may not be a concern
if the AD9851's harmonics (and those generated in any subsequent output
buffer stage) are very low in amplitude.

2) Hand-building couplers and bridges doesn't make much sense when
surplus HP8505-era test sets good to 1 GHz+ are as cheap as they are.
If I were only concerned with HF, though, Paul's approach looks fine.

3) There's no excuse for not releasing the source code to the software,
IMHO. A proprietary closed-source DOS app doesn't exactly lend itself
to customization and improvement. In fact, we'll be lucky if this code
even runs on the next generation of Windows. I'd urge Paul to
reconsider his software strategy (assuming I'm not mistaken about it
being closed-source in the first place).

Pretty darned cool project, all in all.

>that takes place.
>
>My question of "at what point does the carrier start to be effected" I
>was referring to low frequency modulation. Meaning when would you
>start to notice the carrier change.

As long as the AM is less than 100% there won't be any change.

The qualifier there is the MEASURING INSTRUMENT that is
looking at the carrier.

With low and very low modulation frequencies, the sidebands
created will be very close to the carrier frequency. If the measuring
instrument cannot select just the carrier, then the instrument
"sees" both the carrier and sidebands...and that gets into the
time domain again which WILL show an APPARENT amplitude
modulation of the carrier (instrument is looking at everything).

>I don't know how you would observe the carrier in the frequency domain
>with very low frequency modulation as the side bands would be so close
>to the carrier.

DSP along with very narrow final IF filtering can do it, but that isn't
absolutely necessary to prove the point.

Using "ordinary" narrowband filtering like a very sharp skirt 500 Hz
BW filter and variable frequency audio modulation from about 1 KHz
on up to some higher, one can separately measure the carrier and
sideband amplitudes. It will also show that the sidebands and
carrier do not change amplitude for a change in modulation
frequency, which is predicted by the general AM equations. Ergo,
decreasing the modulation frequency will not change amplitude
but one bumps into the problem of instrument/receiver selectivity.
That problem is one of instrumentation, not theory.

>In my scenario of plate modulating a transmitter with a very low
>modulation frequency (sine or square wave), on the negative part of
>the modulation cycle the plate voltage will be zero for a significant

>amount of time of the carrier frequency. The modulation frequency
>could be 1 cycle per day if we chose. In that case the plate voltage
>would be zero for 1/2 a day (square wave modulation) and twice the DC
>plate voltage for the other half day. During the time the plate
>voltage is zero there would be no RF out of the transmitter as there
>would be no plate voltage.

It's a problem of observation again. Even with a rate of 1 cycle per day, the sidebands are still going to be there and the observing instrument is going to be looking at carrier AND sidebands at the same time.

That would be right at 100% modulation, has to be if the carrier envelope is observed to go to zero. At 99.999% (or however close one wants to get to 100 but not reach it) modulation, the theory for frequency domain still holds. Above that 100% modulation, another theory has to be there.

For greater-than-100% modulation, an extreme case would be on-off keying "CW." Sidebands are still generated, but those are due to the very fast transition from off to on and on to off. Those sidebands definitely exist and can be heard as "clicks" away from the carrier. In designs of on-off keyed carrier transmitters, the good rule is to limit the transition rate, to keep it slower rather than faster. [that's in the ARRL Handbook, BTW] Slowing the transition rate reduces the sidebands caused by transient effects (the on-off thing).

Modulation indexes greater than 100% fall under different theory. For on-off keyed "CW" transmitters, the transient effect sideband generation is much farther away from the carrier than low-frequency audio at less than 100% modulation. It can be observed (heard) readily with a strong signal.

>This is where I get into trouble visualizing the "carrier staying
>constant with modulation". As the above scenario, there would be zero
>output so zero carrier for 1/2 a day. The other 1/2 day the plate
>voltage would be twice so we could say that the carrier power during
>that time would be twice what it would be with no modulation and that
>the average carrier power would be constant. (averaged over the entire
>day).
>
>But we know that the extra power supplied by the modulator appears in
>the side bands and not the carrier.
>
>What is happening?

A lack of a definitive terribly-selective observation instrument is what is happening.

Theory predicts no change in sideband amplitude with AM's modulating frequency and practical testing with instruments proves that, right down to the limit of the instruments. So, lowering the modulation frequency

to very low, even sub-audio, doesn't change anything. The instruments run out of selectivity and start measuring the combination of all products at the same time. Instrumentation will observe time domain (the envelope) instead of frequency domain (individual sidebands).

There's really nothing wrong with theory or the practicality of it all. The general equations for modulated RF use a single frequency for modulation in the textbooks because that is the easiest to show to a student. A few will show the equations with two, possibly three frequencies...but those quickly become VERY cumbersome to handle, are avoided when starting in on teaching of modulation theory. The simple examples are good enough to figure out necessary communications bandwidth...which is what counts in the practical situation of making hardware that works for AM or FM or PM.

In the real world, everyone is really working in time domain. But, the frequency domain theory tells what the bandwidth has to be for all to get time domain information. In SSB with very attenuated carrier level, that single sideband is carrying ALL the information needed. We can't "hear" RF so the very amplitude stable receiver carrier frequency resupply allows recovery of the original audio. With very very stable propagation and a constant circuit strength, the original audio could go way down in frequency to DC. The SSB receiver could theoretically recover everything all the way down to DC...except the practicality of minimizing the total SSB bandwidth and suppressing the carrier puts the low frequency cutoff around 300 to 200 Hz.

The carrier isn't transmitted, and it is substituted in the receiver at a stable amplitude in a SSB total circuit. Yet, theoretically it would be possible to get a very low modulation rate but nobody cares to do so. There ARE remote telemetering FM systems that DO go all the way down to DC...but most communications applications have a practical low-frequency cutoff. Theory allows it but practicality dictates otherwise. The same in instrumentation recording/observing what is happening...that also has practical limitations.

If most folks stop at the "traditional" AM modulation envelope scope photos, fine. One can go fairly far just on those. To go farther, one has to delve into the theory just as deeply, perhaps moreso. Staying with the simplistic AM envelope-only view is what made a lot of hams angry in the 1950s when SSB was being adopted very quickly in amateur radio. They couldn't grasp phasing well; it didn't have any relation to the "traditional" AM modulation envelope concept. They couldn't grasp the frequency domain well, either, but that was a bit simpler than phasing vectors and caught on better than phasing explanations. :-)

Basic theory is still good, still useable. Nothing has been violated for the three basic modulation types. Practical hardware by the ton has shown that theory is indeed correct in radio and on landline (the first "SSB" was in long-distance wired telephony).

BLENDING two basic modulation types takes a LOT more skull sweat to grasp and nothing can be "proved" using simplistic statements or examples (like AM from just RF envelope scope shots) either for or against.

I like to use the POTS modem example...getting (essentially equivalent) 56 K rate communications through a 3 KHz bandwidth circuit. That uses a combination of AM and PM. Blends two basic types of modulation, but in a certain way. Nearly all of us use one to communicate on the Internet and it works fine, is faster than some ISP computers, heh heh. So, the simplistic explanations of "one can't get that fast a communication rate through a narrow bandwidth!" falls flat on its 0 state when there are all these practical examples showing it does work. It isn't magic. It's just a clever way to blend two kinds of modulation for a specific purpose. It works.

In the "single-sideband FM" examples, one cannot use the simplistic rules for FM in regards to bandwidth or rate. Those experiments were combining things in a non-traditional way. It isn't strictly single sideband, either, but many are off-put by the name given it.

Why don't you use a language we understand in the civilized world and
ask for R22, alternatively R18 or R24 which at the same time indicate
the frequency. You seldom see such large dimensions, believe they had
waveguide for the over hoizon radio link system on 900MHz, but usually
WG is not practical below 3.3GHz, so I would have expected to find any
value in collecting such (see conversion table and data in RSGB
VHF/UHF Manual)

Nonsense, rectangular waveguide is used quite frequently in UHF television broadcast transmitting installations. Granted it's pretty good sized stuff to get the lower cutoff frequency down where it needs to be in the 450 - 800 MHz range (WR1150, WR1500, and WR1800 for example) .. at least 6" x 12" outside dimensions. But it's definitely practical at those frequencies which are far below 3.3 Ghz.

See http://www.dielectric.com/broadcast/catalogs/RectangularWaveguide.pdf for full details.

if you have any late seventies ARRL handbook. You will find a pair of FM receiver and transmitter that are as simple as it gets.
The transmitter uses just three transistors in the line-up. A transistor array was used instead of discrete transistors for the modulator.
The receiver is quite sparse too, it uses an LM3089. A few sources still stock them. Although you might have a problem getting the audio amp chip, but an LM386 should do the job just as well.

What I would personally suggest is go ahead and start building it from the scratch. Solid State Design listed a transmitter (probably done by W7ZOI, going by the looks of the construction in the picture) for 144 MHz CW/DSB. You can easily add NBFM with just a varactor and using the same modulator circuit (with limiter added).

Once you do have a transmitter going, make a simple VHF down-converter. that works in conjunction with an HF rig. Almost any HF rig can be pressed into 'emergency' NBFM mode by slope detection (tune slightly off the received NBFM carrier). I would recommend the 'rochester' convertors from the 70s handbooks. Later, you can substitute the HF rig with an NBFM IF strip using any of the several NBFM ICs. Check Harry Lythall's home page for the NBFM receiver circuit.

The great principle of homebrewing was laid down by Julius Caeser: divide and conquer. Split it up into smaller, easily managed projects and achieve each on its own.

Build, Test and Measure, Integrate, Repeat.

RSGB Sales may have copies still.
Perhaps also that On-line bookshop would be worth a try.

I've read through some of the replies and didn't see what I thought was a good answer to "where can I find a good explanation". We've been doing a series of technical seminars at work, and one of the first ones covered AM and FM modulation. (FYI...we build equipment that is very good at analyzing spectral content of signals, so it's an area we care quite a bit about.) We used a vector diagram that I think is fairly easy to understand. Wish I could draw it here! I'll try to describe it verbally in a way you could draw it yourself, and think about it.

For AM: Draw a vector starting at the origin and going one unit right. This is the carrier, at time=0. It rotates counterclockwise (by convention) at the carrier frequency. Now consider, say, 50% modulation with some sinewave, maybe 1/1000 the carrier freq. To represent this, draw two more vectors. The way we've done it is to start them both at the right end of the first (carrier) vector. Both are 1/4 unit long. To start, at time=0, draw them both further to the right from the carrier. Since they are both adding to the carrier, the net at that point in time is 1.5 units long. Now if the carrier didn't move (zero freq), one of the little vectors would rotate clockwise and one would rotate counterclockwise, at just the same rates. (Careful here! The one going clockwise represents your "negative freq" if you will, but there is NO MATH, just a picture, so don't let your mind lock up on this one!) They'd get to be both pointing to the left at just the same time, and at that time they'd subtract from the carrier and leave you with a vector 0.5 units long. But before you got to that point, you'd have one of them pointing straight up, and one pointing down, and they'd cancel out, leaving just the carrier. Now just imagine all that happening as the carrier rotates them around... it's all just the same but produces the carrier plus the two sidebands. One key thing to get from this picture is that the two modulation vectors always sum together to a vector which is parallel to the carrier vector (or else zero length).

For FM: Draw the same picture, but now the modulation vectors both start pointing up, at 90 degrees to the carrier. As they rotate around, they always sum to something that is perpendicular to the carrier vector. Hmmmm...but notice that if they are very short, the net result is practically the same length as the carrier vector all the time, but if they are a bit longer, you'd have the carrier amplitude changing. Draw the picture to see that! Let's say that each of the two are 1/10 as long as the carrier, so that the result is a right triangle with the carrier 1 unit long and the modulation 1/5 unit long. So the net in that case would be sqrt(1^2 + 0.2^2) = 1.02. But this is FM, and the amplitude is not allowed to change. So we have to put in a correction. One way to do that is to add a couple more vectors which correct this initial error. If you think it through, you'll see they have to rotate twice as fast as the initial two modulation vectors. So the initial ones represent the first sidebands, and the next pair represent the second sidebands...and if you draw it out right, you'll be able to see how the whole set of sidebands comes about.

So...why is it FM? Because the sidebands rotate the carrier phase. In fact, that's how you have to draw the set of modulation vectors: to sum up to a carrier whose phase is modulated (which is the same as FM, of course, for this single sine freq modulation).

But notice that if the modulation is low enough, practically all the modulation energy is in those initial two sidebands, represented by the first two vectors. Now if you transmitted ONLY those two and removed the carrier, and someone on the other end inserted the carrier at t=0 pointing UP instead of to the right, why you'd have -- AM! Or at least something very, very close to AM. So, I think it should be clear from that, that single sideband FM (assuming very low modulation index) should be practically equivalent to single sideband AM.

By the way, back several years ago there was a lot of interest in finding ways to make more efficient AM broadcast transmitters. If you use a class C power amplifier, you can get good RF-generator efficiency, but the modulator running class AB or B is inefficient. And if you do the modulation at a low level, you have to run the RF chain AB or B. So one of the ways invented to get AM was to generate two FM signals, which of course can be amplified by class C power amps, whose modulation was generated through a pretty special DSP algorithm, so that when you combined the RF outputs of the two FM transmitters you got, ta-da, AM! I always thought that was pretty cool, but I don't think it ever caught on in a big way, because folk have come up with other ways of efficiently generating AM.

Cheers,
Tom

Rectangular waveguide below 1 GHz (which is above UHF TV)?

Coaxial structures, yes, especially for the visual-aural diplexer.
I've walked INTO the channel 13 diplexer for KCOP on Mount Wilson
(serving Los Angeles with 50 KW into the antenna). Just open the
door in the corner formed by the visual and aural transmitters and
one comes upon a massive array of round structures...:-)

General Electric used rectangular guide based filters for their 1.8
GHz microwave radio relay diplexer, a 1950 design. Efficient as a
multisection pair of narrowband bandpass filters for its time. Big,
though, was as long as four racks are wide.

At a PGMTT meeting in Santa Monica I once heard an informal
chat about three guys using air conditioning duct at high UHF in
lieu of buying special waveguide. It worked at low power. Think
about it...some standard ducting comes in 2:1 width:height ratios
just dandy for TE_1_0 mode. Heckuva lot cheaper than buying
specific waveguide at the same size...probably cheaper than used
waveguide (if such is available).

When I first read this, I though you meant that you were ***inside*** of the
diplexer [hopefully not while it was 'on the air'] :-) Then I reread it,
and understood what you meant. Yes those coaxial cavities can be quite
impressive.

2984. AD995X series DDS, rig ideas

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-26 19:59:17 UTC
From: kenneth scharf <wa2mze-spamnot-@bellsouth.net>
Message-ID: <3F9C2795.90708@bellsouth.net>
Source record: 31451

I just got some samples of the AD9952 and AD9954 DDS chips.
Both look identical, AD9954 has some extra features I don't need
but can simply not program. These parts are real small, will have
to find some VERY small tweezers to bend the leads and file down
a soldering tip to fit. I would try to solder all the gnd and unused
inputs down to a PC ground plane and bend all the power pins up
flat against the top of the chip to be soldered together. The signal
pins would have to be bent up halfway and fly leads soldered on
to go to the rest of the circuit on perfboard.

Anybody try to breadboard one of these 'dead bug' style like this?
Anyone have some circuit advise on using these chips? I am thinking
of using one in a single conversion transceiver. Mixers will be
DBM using push pull digital drive so the DDS will drive a 74xx74
divider and be driven at twice the LO frequency. (several examples
of such receiver front ends in recent ARRL HB's). IF will be 9mhz,
I have 4 identical 9mzh filters, so will use 3 in rx if and 1 in tx.
(got those filters at Dayton about 10 years ago... Clegg surplus).

Was thinking of using 8051 series micro, the built in serial port will
drive the AD98xx and AD99xx dds chips. Question....how do I convert
the 5v digital io of the 8052 micro to the 1.8v levels used by the
AD995x series, or is the DDS chip 5v compatible (on input maybe...
what to do about output? especially on the bidirection serial line....)

Was also thinking about maybe building the rig as a 6 meter single
conversion with an HF transverter front end. What do you think of
this idea?

Message-ID: <3F9C325E.60C85F5C@cox.net>
Source record: 31452

I have mounted the 9850 and 9851 chips dead bug like this before. It is an extremely painful process, but doable. Be very careful with the leads, I had one of the pins of a 9851 break off. You really only get to bend a pin once. Don't try bending it twice! I have mounted a lot of DIP and SOIC chips deadbug and have almost never had a pin come off (ok, maybe once, but it was kind of abused), but TSSOP packages such as this are more fragile.

Except for the ground connections, which I bend over for direction connection to the ground, I bent every other pin either up or out a bit to get a little more space for the connections. I used #32 gauge enamel wire for interconnect. When mounting the device, pre-tin all leads in advance and tack the device in place by soldering the ground leads, and connecting the power leads via bypass caps.

When making a connection to the part or wire to the chip, pre-tin the part and touch solder the part or wire to the pin. This is very difficult as the heat from the tip can melt an adjacent connected wire or part.

It is easy to create solder bridges across pins. Solder wick or a solder sucker, or an exacto knife can be use to open up such a bridge as the solder is heated with a iron. Some time a bit of fresh solder with fresh flux helps undo the bridge.

Patience, patience, patience!

It is difficult to do, but it can be done, and the results can be quite rewarding.

As far as 5v to 1.8v logic level conversions, the very simplest thing is to use a 2N7000 MOSFET transistor for each signal. The gate can be directly driven with the 5v signal, and the output can be pulled up to 1.8v with a 2.2K resistor. It is cool to deadbug with the surface mount version of these parts (SOT-23) and use a 805 size chip pull up resistor. The resulting "inverter" in very small! The signal will be inverted, but just keep that in mind when writing the software.

I use the surface mount FETS (BSS123/2N7000) in the receiver diplexer in my home brew transceivers, and they don't take up much space!

2988. LOC/VOR Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-26 22:25:14 UTC
From: Pawe&#65533; Stobi&#65533;ski <NO_sq9nry@wp.pl_SPAM>
Message-ID: <bnhe10$73v$1@julia.coi.pw.edu.pl>
Source record: 31455

Hi;

I've recently bought two aircraft rx modules, there's only 'LOC/VOR receiver' written on the chassis, neither manufacturer nor any additional infos. Single aerial input, and several connectors. As I inspected, it is a complete 108-117MHz rx, with RF amp, LO, mixers, quartz filters, and demodulator. One of them (1990) is equipped with a PLL synthesis, and the other (1975) has 10 switched crystals instead. Whole RX is a metal, rigid can (as for high-end devices used in aircrafts). Unfortunately, I haven't found any documentation concerned with it. The schematic diagram would be the best, however I suppose this stuff is not widely available. Nevertheless, if anyone had any info how to connect such things or make them work, would be appreciated. Of course, I can redraw the wiring; although that could take weeks :)

Cheers,

2989. Re: Single Sideband FM

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-26 22:30:01 UTC
From: Gary Schafer <gaschafer@comcast.net>
Message-ID: <viiopvo9dsogqm2n4ff587h5p4eqjjqak1@4ax.com>
Source record: 31456

Let's start at the other end and see what happens;

If we have a final amp with 1000 dc volts on the plate and we want to plate modulate it to 100% or very near so, we need 1000 volts peak to peak audio to do it.
On positive audio peaks the dc plate voltage and the positive peak audio voltage will add together to provide 2000 volts plate voltage.

On negative audio peaks the negative audio voltage will subtract from the dc plate voltage with a net of zero volts left on the plate at that time. (or very nearly zero volts if we do not quite hit 100%)

How does the tube put out any power (carrier) at the time there is near zero plate voltage on it?

The negative audio cycle portion is going to be much longer than many rf cycles so the tank circuit is not going to maintain it on its own.

Why does the carrier stay full?

I'm a big fan of these tweezers: http://www.folica.com/removal/rubis_costwe132.htm They have the finest tips I've ever seen, and are great for working with these sorts of parts.

> I would try to solder all the gnd and unused

Note that TQFP pin spacing (0.5 mm) is half that of the AD9850/AD9851 chips that Dan Tayloe mentions. Still, it can be done, and your strategy sounds reasonable. I have hand-wired several 16-pin TSSOP 0.5-mm chips by hand without losing one. Solder-wick and a fine-tipped iron are mandatory. As Dan says, you can count on being able to bend each lead only once, so make sure you get it right!

On the plus side, these chips appear to be very hard to overheat in the soldering process, probably due to low lead mass and stout internal connections. You can afford to take your time.

It might not be an issue with 1.8V logic, but these chips' 3.3-volt predecessors (the AD9852 and AD9854) really got hot when operated near their maximum clock speeds. On a PC board, the traces offer a definite heat-dissipation advantage over hand-wiring. Don't assume you can run these chips full tilt until you verify that they don't overheat in your dead-bug configuration.

> what to do about output? especially on the bidirection serial line....)

Just use a resistive divider. I don't see any reason to use FETs unless programming speed is a concern. (CMOS inputs look like capacitors, so resistive dividers will slow your signal edges down and limit the speed at which you can program the chip. Some CMOS parts have a minimum-risetime requirement, but I haven't bumped up against it yet personally except for Vcc pins.)

I see in the data sheet that the I/O pins can be configured for 3.3V logic levels, so that might help.

> test sets that have directional couplers, etc that are good for HF.

HP 8503A is the 50-ohm S-parameter test set, good for ~40 dB directivity
from near DC to 1 GHz.

HP 8502A is the 50-ohm transmission-reflection test set, with a similar
frequency range.

The 'B' suffix refers to 75-ohm versions of these units.

>http://www.andrew.com/search/docviewer.aspx?docid=398

I'm not going to say it can't be done or even shouldn't. :-)

Rectangular guide at TE-sub-10 mode is convenient to use
in general applications. Except for the choke-joint flanges, it
is fairly easy to fabricate, even in the home workshop; think
raw PCB stock for stiffness and easy solderability or other
sheet metal joined with a copper-pipe-plumber's torch. The
launch probes are also mechanically easy on fabrication.

In circular waveguide, there's a different mode choice and
you can't fabricate that easily in the home workshop. Also

the I/O structures are a bit more difficult for the hobbyist.

I'm not going to drag out the Matthei for this but the above is
looking at practicality.

Andrew is a good company and has been making antennas for
a while. I got very intimate with their 10 foot dishes back in
1954...:-) But then they were using 1 5/8" rigid coax feed,
pressurized over 250-foot length of terminal to antenna.

>impressive.

KCOP does the 24/7 bit now as it did in 1958 when a buddy and I got
a tour of it. It was ON when we stepped into the collection of large-
scale plumbing. Not a problem. Two transmitters at right angles,
diplexer at the corner. At the time their older transmitter was on the
other side of the transmitter room, ready to use in case of main xmtr
catastrophe...forget how the antenna connection switchover was done
although it was explained (I'll blame the altitude...Mt. Wilson is about
5700 feet ASL...:-).

Most TV broadcasters don't mind interested viewers visiting their
stations if one calls ahead. Remote transmit sites don't get a lot of
activity. Mt. Wilson for Greater Los Angeles coverage is an exception
with over two dozen transmitters along with a solar observatory, a
couple hotel/motels, and the beginning of a national park area.

Since I was thinking of using a fair sized piece of PC board as a ground
plane
to which ALL the gnd pins would get soldered to, I might have a good enough
heat sink. I could also put some silicon heat sink grease on the bottom
of the
chip, or glue the chip down to the pc board with heat conductive epoxy.

Jan-Martin -

I found at interesting web site for a Japanese accelerator using 108 of
these transistors producing
20 kW of power !!

Here is a photo of 8 of these for a 1 kW + amplifier at 144 MHz (JA0TJU)
http://www.ginzado.ne.jp/~hamradio/tju/2c3286.htm

The transistor package is a Gemini (2 transistor chips mounted for push-pull
operation)
Produces about 200 watts at 200 MHz. The transistor appears to have been
developed
for solid-state modules in TV transmitter usage.

>found any documentation concerned with it. The schematic diagram would be
>the best, however I suppose this stuff is not widely available.

If you can give us some sizes (mm or cm okay) and describe the other
(not coaxial) connectors pin count or connector identification, it would
be a start. If this was used on air-transport aircraft, the box sizes,
connectors, and connector pin functions are all standardized under
ARINC specifications. ARINC documents are available from them but
are very expensive to order from that industry group. The cabinet/box
sizes are described by "ATR-x" and slide into aircraft racks (also
standardized) and lock down through bottom front end pins.

>Nevertheless, if anyone had any info how to connect such things or make them
>work, would be appreciated.

VOR (Very high frequency Omnidirectional radio Range) uses a
combination of AM at 30 Hz (from the ground station antenna pattern
actually rotating at that rate) and a 30 Hz signal derived from FM
demodulating a 9.96 KHz subcarrier as the reference phase for azimuth
bearing to the ground station. There are many ways to show or compare
the two 30 Hz phases (automatic or semi-manual) and would be done in
a pilot's OBS or Omni Bearing Selector, usually a separate panel
mounting instrument. The "open space" from 30 Hz to near 10 KHz can
be used for voice audio from the air traffic controller to the aircraft or
for
automated airport condition recordings.

LOC or Localizer is also a sort-of azimuth bearing radionavigation
system but is specifically for the approach path azimuth for landing.
Uses only two tones and compares the amplitudes (equal when
centered on approach path). In most OBSs, the "left-right" needle
is switchable to either VOR or LOC but the audio signals for each
function are different.

From the basic VOR function, the receivers would have a 10 KHz
minimum bandwidth and tune 108.20 MHz upwards in 200 KHz

increments. LOC tunes from 108.10 MHz upwards in odd increments, interleaved with VOR. Note: Later ICAO (International Civil Aviation Organization) specifications may have 50 KHz increments in some countries, but the even-odd interleaving still holds. AM demodulation for both receivers.

If your receivers are modules that fit into a larger one, the full documentation would have to come from the manufacturer. Nothing secret about it...just isn't widely used outside of the civil aviation world.

ARINC was first organized before World War 2 in the USA as a private airline communication company ("Aeronautical Radio, INC") but became a non-profit industry standards group after the war, principally for airlines and air transport companies to allow very quick substitution of standard communications and radionavigation radios and indicators anywhere in the world.

> Of course, I can redraw the wiring; although
>that could take weeks :)

If you can't identify the receivers from existing website manufacturer's photographs, that might be the unfortunate necessity. Try a search on the Internet using "aircraft radionavigation radio" and see if anything comes close.

Personal story: In 1947 at age 14 I got started in "real radio hardware" by having to generate a schematic for the ARC-5 airborne radios sold as military surplus...the new store owned by two long-time hams did not have a reproducible schematic for less than a few dollars. Took me a week-plus to do it as a beginner using an ordinary multimeter. By then the store had obtained copies of the schematics, selling them for much less than originally...:-) It was good training for me at the time. In 1981 another engineer and myself had to generate several schematics from existing PCB assemblies because a project manager refused to spend extra project money for documentation. Together, we cost the project a LOT more than the documentation and wasted a whole month. :-)

Gary, you are trying to mix the frequency domain and time domain information...and then confusing steady-state conditions in the time domain with repetitive conditions.

The "carrier amplitude is constant" holds true over repetitive audio modulation. In conventional AM, with repetitive modulation from a pure tone, there are three RF spectral products. If you deliberately notch out the carrier component in a receiver, and then reinsert a steady-state, synchronized carrier frequency component in its place, you will recover the original modulation audio. The receiver demodulator sees only a steady, constant-amplitude carrier frequency component. There is absolutely no carrier amplitude variation then. But the original modulation audio is demodulated exactly as if it were the done with the original transmitted carrier. SSB reception is done all the time that way (except the carrier amplitude is so low it might as well be zero).

That's a practical test proving only that the carrier amplitude does not have any change insofar as demodulation is concerned.

As a practical test of just the transmitter, let's consider your basic old-style AM description...Class-C RF PA with linear plate volts v. power output characteristic, modulation by the plate voltage. That

plate voltage is 1 KV steady-state. In steady-state, RF output has a single RF component, the carrier frequency. One.

RF spectral component will follow the general time-domain RF equations with no modulation. [easy math there]

Apply modulation to the plate voltage with a pure tone. Plate voltage swings UP as well as DOWN equally. [theoretical perfect linear situation] Same rate of UP and DOWN. [start thinking dv/dt]

Look at the spectral components with this pure tone modulation. Now we have THREE, not just one. Any high resolution spectrum analyzer sampling the RF output will provide practical proof of that.

So, if you want to examine the total RF in a time-domain situation, you MUST examine it as amplitude versus an infinitely-thin slice of TIME. You cannot take a finite time chunk out of the RF envelope and "prove" anything...anymore than you can justify the existance of three RF components, not just TWO. [if this were the real classroom, you would have to prove that on the whiteboard and justify it in full public view...and maybe have to show the class the spectrum analyzer output]. Remember that the modulation signal also exists in a time domain and is constantly changing.

If the "carrier sinewave goes to zero and thus power output is zero," how do you justify that, a half repetition time of the modulation signal later, "carrier sinewave goes to twice amplitude and power output is double"? You are trying an analogy that has a special condition, by neglecting the RATE of the modulation. It is always changing just as the carrier frequency sinewave is changing. You want to stop time for the modulation to show repetitive RF carrier sinusoids and that is NOT modulation. It is just adjustment of the RF output via plate voltage. No modulation at all.

The basic equation of an AM RF amplitude holds for those infinitely-small slices of TIME. The series expansion of that basic equation will show the spectral components that exist in the frequency domain. Nothing has been violated in the math and practical measurements will prove the existance and nature of the spectral components.

For those that like the vector presentation of things, trying to look at a longer-than-infinitely-small slice of time or just the negative or positive modulation swings is the SAME as removal of the modulation signal vector. Such wouldn't exist in that hypothetical situation. It would be only the RF carrier vector rotating all by itself.

In basic FM or PM, there's NO change in RF envelope amplitude with a perfect source of FM or PM. "The carrier swings from side to side with modulation," right? Okay, then how come for why does the carrier spectral frequency component go to ZERO with a certain modulation/deviation level and STAY there as long as the modulation is held at that level? RF envelope amplitude will remain constant. Good old spectrum analyzer has practical proof of that. [common way

of precise calibration of modulation index with FM] The FM is "just swinging frequency up and down" is much too simple an explanation, excellent for quick-training technicians who have to keep ready-built stuff running, not very good for those who have to use true basics for design, very bad for those involved with unusual combinations of modulation.

If you go back to your original situation and have this theoretical power meter working with conventional AM, prove there are ANY sidebands generated from the modulation of plant voltage...or one or two or more. :-) Going to be a difficult task doing that, yet there obviously ARE sidebands generated with conventional AM and each set has the same information. Lose one and modulation continues. Prove it solely from the time-domain modulation envelope. Prove the carrier component amplitude varies or remains constant.

Hint: You will wind up doing as another Johnny Carson did way back in 1922 (or thereabouts) when the basic modulation equations were presented on paper. [John R. Carson, I'm not going to argue the year, that's in good textbooks for the persnickety] With conventional AM the CARRIER FREQUENCY COMPONENT amplitude remains the same for any modulation percentage less than 100. Period. I not gonna argue this anymore. :-)

That could be a problem - I do not posess any digital camera to take a photo. If it's about the device - an ordinary, rigid, metal box, 40x10x2 cm. There are a few holes to make necesary adjustments (IF AGC, RF AGC) too. If it's not any help, will try to find a cam, anyway.

You might want to remind everyone that the mathematical Fourier transform of a signal is an integral that extends from time=minus infinity to plus infinity. Since Real Spectrum Analyzers (or network analyzer) need to produce results in something, oh, less than infinite time (probably less than the time between now and the next donut break), they're necessarily limited in the low frequency detail they can provide. True, if Gary's transmitter is transmitting a zero at the moment he connects a spectrum analyzer, he won't see anything at all on the display, but as you point out -- this is an equipment problem, not a mathematical one.

I'm still a believer in SSB-FM, BTW. :-) But I have enough respect for you that I won't attempt to argue it further without first finding the time to prepare a few drawings to demonsrate why!

The series expansions of the basic modulation type RF time-domain
expression don't use Fourier series. The series expansions show
the sprectral content are still equivalent to that infinitely-thin slice
of time as the function of amplitude.

I think that Panters "Signals, Modulation, and Noise" text has it
worked out in there (by memory, don't have that one handy here).
The "Landee" text I mentioned is an old one and not that familiar
to most.

No, it's an argument problem. :-)

There's no infinitely-fast RF power meter in existance. Yet.

I'm not arguing that "single-sideband FM" won't work. I just don't like
the name. The technique DOES work from all the explanations of
experiments, is reproducible. [it isn't the "cold fusion" thing. :-)]

I've not seen any convincing case that the single-whatever FM thingy
has any practical applications.

For narrowband voice, SSB AM is just dandy and a phasing system
using the Gingell-Yoshida polyphase network is quite easy and

error-tolerant to make a good phasing exciter. It can be used in "reverse" to get an easy-to-select sideband demod or an ordinary AM detector that yields false stereo (one sideband to each ear), already done with simple CW receivers.

...or real stereo! The Kahn/Hazeltine AM stereo sysem did this -- L in the lower sideband, R in the upper. Hence envelope detectors recovered L+R, and AM radios built back to the beginning of (radio) time kept working.

On the other hand (and I know this is just asking for abuse), the Motorola C-QUAM AM stereo system could be applied to SSB modulation and still work, which obviously Kahn/Hazeltine can't. I don't imagine C-QUAM's designers were considering this, however.

It's almost painful to look at the (complex) envelope of AM and notice that the quadrature signal is completely unused. Sending stereo over I and Q strikes me as a 'interesting,' (does anyone know of a commercial system that does this? Surely somebody's must...) but of course it would break compatibility with current receivers and I imagine someone who's more knowledgeable than I could point out some pitfalls as well.

Where can I find good information about the principle and the design of linear power amplifier using semiconductors, up to the full legal power limit ?

Is it only possible to use power splitter ? I have seen broadcast transmitters in the power range of many hundred of kW's, having an power efficiency of more than 90 %. Do they use power splitter or another design ?

The biggies for AM are often essentially huge D-to-A converters.

The FM ones use splitters and combiners.

Neither are linear amplifiers.

First, you should have references to Helge Granberg (sk) work when he worked
at Motorola.
His work can be found in several Application Notes and a book he wrote with
Norman Dye.

RF Transistors (about 1/2 down this web page)
http://www.rfparts.com/tranbook.html

Motorola Application Notes (this is a subset on CCI web site)
http://www.communication-concepts.com/application_notes.htm

JA0TJU is an excellent resource and reference for "broadcast style"
construction
http://www.ginzado.ne.jp/~hamradio/tju/2c3286.htm

DL4MUP has this article (may not load), he references the earlier work of
W9NUP
http://www.qsl.net/dl4mup/UKW45/UKW45_w.pdf

W9NUP, Ron Purkey article in Issue 3 of the 1999 VHF Communications magazine
on "Another RF Combiner / Splitter".

He built a 1 KW VHF amplifier using 4 MRF 141G modules with a splitter and
combiner running 28v @ 60+ amps.
The amp takes approx 50 watts to drive.

This was NOT the normal "rat race" type of combining, but rather based on
Myat Engineering E*Star (which is a European firm).
Any number of odd or even modules may be employed, making it nice for
growing as can be afforded.

I understand Myat took down their informational Internet web site after this
article appeared (too many hits and questions)

Here are pictures from the K5OE web site

I need around 20amps to run my mobile HF rig in the house. I have lots
of old PC switching power supplies that put out 8 - 10 amp @ 12v
without any problem.
Im wondering if anyone has ever had any luck connecting two or more
in parallel
to increase current ? Ive thought of adding a stud mount diode in the
positive
leads to isolate them and connect the commomn or neg togather. I can
raise the voltage to makeup for the .6 volt drop without any problem.
Not having alot of switching supply experience, Im wonder if this
will work or
just go up in smoke?

It should work except that these power supplies generally won't start up unless there is a substantial load on the +5 Volt line. I suppose you could put a load on that line and when the output stabilizes, reduce it to a negligible value with a relay or something.

Radio gear designed for 12 Volts often won't deliver full output unless the supply is at around 13 Volts or more. Check your own gear and see what it takes to work properly. I like running my rigs at around 12.5 to mazimize lamp life but that doesn't work with one rig, the IC-751, which won't put out the full 100 Watts unless the supply is above 13 Volts.

73, Bob

I wouldn't recommend it. There are computer power supplies made for
N+1 hot swapping that will work well in parallel, but they are designed
for that application. Look around for a surplus power supply big enough
to handle the radio.

I see an obvious problem in the schematic.

You show two separate transformers labelled T5. One is clearly a trifilar device, in your two-diode balanced mixer. The other is clearly a bifilar device, coupling output from the IRF510 final into the output filter. You probably want to fix that nomenclature, and add data for the RF output transformer.

Also, I'm curious. Why did you use 2N3866 everywhere, instead of, say, PN2222A (plastic 2N2222A)?

You can probably make it work with matched parts, but you will need somevery good heatsinking and a crowbar circuit in case one of your pass regulators shorts out.

You should really look at using an ASTRON SS30 or SS30M (M has volt and amp meters). One was for sale on one of the swap boards recently. I have two and they deliver the current without any strain or heat. As far as RFI noise, they are also very quiet. ARRL did a write up a couple years back on various switchers and this one was the quietest. 25 amps continuous, 30 amps intermittent. I run mine to 20 amps all the time and the fan switches on for a short time, no sweat.

3016. Newbie qrp homebrew....another update

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-28 05:35:16 UTC
From: XJohn_S_Sandin@osca.state.mo.us
Message-ID: <3f9dfdbb.2337199@news.kcnet.com>
Source record: 31483

The link below shows my attempt to build a 3-watt transmitter for 40 meters or 80 meters, based on an article in QST, June 1967 and an adaptation thereof by KC6WDK.

http://www.kcnet.com/~oyster/transmitter/transmitter.html

I've had some success since I posted last, but I want to get the output clean before I go on the air with it. I've had very little spare time, but I've managed to improve the performance quite a bit, through a lot of frustrating trial and error.

The good news: The transistor does not become egg-frying hot anymore. Now it's just barely warm. I began trying the suggestions about grounding and parts placement provided to me by the good people at rec.radio.amateur.homebrew and qrp-l. What seemed to help the most were the grounding suggestions; I moved several components' chassis connections to within an inch of Q2's emitter, and that seemed to help to increase the output and decrease the self-oscillation, which can now be eliminated via the variable caps for the oscillator and amplifier stages (C1 and C2). I also realized how close the crystal was to Q2 in my original assembly, so I moved the crystal over near the oscillator section, and that seemed to help, also. The chirp is still a little bothersome, but the transmitter appears to be putting out around 2 watts into a dummy load, sans lowpass filter.

I got good results by isolating C2 from the chassis, and grounding it via a separate wire to the point where Q2's emitter is grounded.

I'm having quite a time trying to get rid of harmonics, which I'm "measuring" using my Icom R71A receiver, which is across the room from the transmitter now. Slowly but surely I am making small modifications resulting in small improvements. I'm rebuilding the coils now. More details and new pictures of the rebuilt transmitter are on the website. Thanks to all who offered advice, and any further advice is more than welcome.

john and others -

tnx for the corrections. i also forgot to put the half-wave filter's specs and couple of other subtle typos. i am trying to assemble the second prototype (the one in the picture) refering to just the schematic on the web, to check if things are proper. i will post the corrections soon.

what i did discover about 2n3866 vs. 2n2222 was this: the 2n2222 is mostly used in low frequency switching applications in india. therefore, slimy manufacturers change the markings on other lower frequency transistors and palm them off as 2n2222. the BF194s that i have used extensively is a close plastic cousin of 2n2222 that is used as self-oscillating mixer for shortwave radios in india. It does a reasonable job at HF frequencies if you are not too particular about performance.

The 2n3866 is used in india by the cable TV industry for boosting the line signals. We ordinarily get about 70 channels through the cable (at $3 per month, including HBO/Discovery etc.). The 2n3866 has to keep intermod to a minimum. therefore, we get fairly good quality transistors as far as '3866 is concerned.

in anycase, you will see that the post mix (which should have used a 220R as the emitter bias resistor instead of the wrongly shown 560) needs to be a large signal transistor. I tried with a 2N918 first, as the post-mix and noted an immediate increase in the background hiss (compared to the 3866). I tried the BF194/5 and found it was easily overloading from the computer noise (i am using a PC-based scope). I tried also a BD139 as the post-mix(a 15 watt hifi audio beast with Ft of 150 MHz) and found it to be very noisy.

The circuit uses feedback and degeneration quite extensively, so I urge builders to try different transistors. Most should work, some better than the others. You can also try paralleling two 2n2222 with separate emiiter bias (diving the current in half between them) for the driver feeding the IRF510.

also, i am sort of giving up the idea of making the txcvr multi-band. the bandswitch is a pain. and the transciever costs about $10 in parts here in india, so i might as well build one for each band upto 21MHz.

oh, btw, the local spares shops say that the IRF511 has been discontinued. is it true?

==========
Another consideration is to use a 12 V lead acid battery (sealed) and a say
8 Amperes charger set at 13.8 V. being 1 PC -SMPS

The peak current required for 100 Watts RF operation might be 20 Amperes
,but the average current for SSB during tx is below 8 Amperes ,even when
applying compression. With the current required during rx around 2 Amperes
,the overall average current will probably not exceed 6 Amperes.
With this setup the voltage will hardly drop below 13 volts ever.

An additional advantage of having such a supply system is emergency
operation during an AC power outage. In the latter case you should consider
a large marine type of battery of say 110Ah.
If prolonged operation during an emergency is an important aspect , the
addition of 1 or more solar panels would be beneficial if not essential.

John

Congratulations. It's great to see your progress and thank you for sharing.

Chirp is a fairly common problem, and it almost always has to do with the voltage on the oscillator.

Even though QRP rigs don't draw much current, the inrush on key down can cause the voltage to drop quickly. The first thing to do is to beef up the wires from the power supply to the rig, and keep them short if possible. You might only be drawing an amp on key down, but #12 wire from the power supply isn't overkill, even larger if your run is more than a couple feet. Keep the power wires as fat as possible right up to the oscillator. If you are using batteries and they are getting a little stale, the internal resistance of the batteries could be working against you, as well. Fat wire is pretty reasonable at home supply stores like Lowe's or Home Depot, but generally you want stranded wire as it's a lot more manageable in the larger sizes, tho the solid wire is easier to get.

If that's not adequate, the next move is to regulate the voltage to the oscillator. Some rigs even go to the extreme of adding double regulation to the oscillator. The messy bit is that three terminal requlators need at least a couple of volts extra to do their work. Your supply appears to be 28 volts, so if you were to go with 2 regulators (maybe overkill) then you would need to fiddle with yout oscillator to get it to work at around 20 or 22 volts, instead of 28. Actually, you might consider dropping the oscillator supply below that. After voltage drop, the next most common cause of chirp is heating of the oecillator components, so reducing the energy in that part of the circuit is a good thing. Recognize, though, that changing that voltage means you would need to recalculate the transformer at L1/L2 to account for the new output impedance.

Rich harmonics generally occur as a result of driving the amplifier too hard, although your output pi network could be off, as well. Before getting too carried away, however, keep in mind that even with a clean transmitter, you will hear some harmonics on a radio in the same room. You would like the harmonics to be down at least 40 or 50 db, so if you can transmit into a dummy load and get your receiver far enough away that the fundamental is on scale of the S meter, then you can assess whether the harmonics are in the right neighborhood.

..

That should work OK. If you want a regulated supply then connect the
regulator after the combined DC
voltages. That way you don't have to be concerned with the possible
reverse current through one
of the regulator circuits.

Why don't you connect the transformers in parallel and rectify /
stabilize the total AC current?

Well provided the distance is only few cm it is usually better
pictures than digital camera. I made much efforts to photograph labels
on rigs with my Olympus C-220 Zoom, but didn't succeed until I put the
rig into the scanner, hi, but when using scanner or digital camera it
has always been neccessary to treat the picture with a photo program
to resize, crop, rotate, and adjust the light and contrast

Connecting transformers in parallel is sometimes a risky business, the
only way to do it around here is to use two 117VAC transformers with
primary in series and secondaries in parallel with 230VAC input -
which I am told is also available in many US homes

Hi there .
I wonder if anyone has any suggestions as to how I can stop sub miniature toggle switches from melting , with the heat that is produced , during the curing and setting process of me using potting compound ,

I don't mean physically melting , but I suppose it heats up and distorts , and makes the switch very stiff to operate until eventually it is useless .

I have thought of wrapping it with self-algmating tape before I put the resin in the box .

any suggestion , welcome ??

de Paul

Paralleling DC supplies can be problematic if they are regulated supplies and not designed for paralleling. Another solution to consider is using a deep cycle battery and a charger. Works fine, even during a power outage...

There is a "chance" that the voltages won't be exactly the same. As a result you can
have circulating currents in the transformers from that difference. The diodes solve
that potential problem.

Message-ID: <BBC4682F.87EE%wd0hco@ev1.net>
Source record: 31496

After 31 years and a bunch of parts in the garage, I am finally building my dream CW receiver from scratch.

Just wondering if I converted the 6.3 VAC filament voltage to a DC voltage if doing so would be worth the effort to reduce hum.

Opinions ?

Also I would like to cut a round 4" diameter hole in the 1/8" aluminum front panel for the speaker grill. Is there a way to do this without a Greenlee Pneumatic punch? I have a jig saw which I can cut square holes but round holes are another matter. Is there a better way? I can drill round holes up to 7/8" with a unibit but I think 7/8" is as big as they get.

Thanks

I'm curious... with the current popularity of simple (e.g., QRP usage) direct conversion receivers, whatever happened to the problem of having to synchronize the cariier phases? I'm looking at Experimental Methods in RF Design, and they just use an LC oscillator for the input to the mixer. If input carrier is cos(f*t) and the LC oscillator is generating cos(f*t+phi), where phi is the phase offset between them, you end up with a cos(phi) term coming out of the mixer. If the frequencies are ever-so-slightly off, phi essentially varies slowly and cos(phi) should slowly cause the signal to fade in and out.

Why isn't this a problem in practice?

Thanks,
---Joel Kolstad

This is indeed what happens only if the VFO and an incoming single are
at almost the same frequency ("zero beat"). However, in practice, if
the signal is a cw signal, we listen to a signal that is 600 Hz or so
away from the VFO so that we hear the 600 Hz tone difference.

For a SSB signal, we listen to the audio content contained in the
sideband, which is 300 Hz to 3 KHz away from the VFO signal when it is
tuned in correctly.

I would try making a shell of some sort to create a small airspace between the switch body and the potting compound.

Maybe some sort of small plastic cup, or something made from tinfoil type material.

I did it with 2 of them and it worked OK. As you described use a
separate rectifier on each and combine the rectifier outputs.

Start scrounging hamfests, etc. for electrolytic capacitors. You
can't have too much filtering. In this case more is better.

For a regulator use a 7815 IC to drive several 2N3055's. ARRL
handbooks have a good example of 2N3055's in parallel. 5 2N3055's on
a decent heatsink will run nice and cool. Scrounge for heatsinks,
too. They tend to be cheap at hamfests because most people are
appliance operators.

And if you want to make life easier for the rectifiers add a soft
start cicruit using a relay. The handbook has an example of it.

Good luck and 73,
Jim

I don't know about the VOR rig in question, but UL in the USA requires that
PC boards have a manufacturer's identification. Perhaps, being a
professional, not consumer, item, the boards do not carry ID.

>Connecting transformers in parallel is sometimes a risky business,

Some big power distribution transformers are sometimes connecting in parallel with some external inductance to reduce the imbalance.

Take a separate smallish transformer with a centre tapped low voltage secondary winding. Connect the centre tap to the load and the two end of the small transformer to the respective hot terminals on the main transformers. The primary of the smallish transformer is not connected, but can contain quite voltages.

A similar approach is used when hot switching between different taps on a large power transformer. Normally the two ends of the CT coils are connected to the same tap on the main transformer. Then one end is moved (break before make) to the adjacent tap and after a while the other end is also moved. In this way, the power distribution is not interrupted when changing main transformer taps and it does not cause momentary short circuits on the main transformer.

You are cool, John. I checked your site.

It of course makes you appreciate the engineering which goes into a modern radio. It also gives you a sense of accomplishment when you make it work -- and you will.

I used to do a lot of playing around with the stuff -- not because I enjoyed it then -- just because I was trying to make junk work. Not it seems like it would be fun again.

Good luck.

I thought the ones with the rotating arm were intended for use with a
drill press, not for a handheld drill.

There is a lot of torque from that lever arm, and a moment of
inattention could result in serious injury.

A hole saw is far safer with a handheld drill. Make sure you get one
that will work with metal, though, the wood cutting ones only do wood
and some plastics.

A 7815 would give 15 volts, wouldnt that be alittle high? A 7812 would be a
little low, so i thought of a 723 ang just adjust the voltage to 13.8.

If I did this I would put a 0.01 uF capacitor to ground at each
filament pin, to keep RF from propegating through the wires. I would
also put a resistor to ground somewhere in the string to bleed off any
stray leakage current (maybe 1000 ohms or so), otherwise you might get
voltage buildup that could cause problems.

What about an inadvertent short between the cathode and filament?

Try using some foam tape over the switch assembly before applying the pot compound.

Another solution is to use a cold compound instead of heat generating pot compound.

You get 15 - (transistor drop + balancing emitter resistor drop). I
got 14 volts out of it. That's in the range of car charging systems
and I've measured that much on some cars with the engine running.

There's another setup where you get IC regulator voltage + transistor
drop + resistor drop, using PNP transistors. Check the handbook for
details. Power PNP's are less common and it's hard to beat the
venerable 2N3055's price and availability.

How about a LM317? As I recall they are good for more current than
723's and easy to use. Regulator current at the IC is

(output current) / (transistor gain)
Then you can adjust to get 13.8 on the output.

73,
Jim

>little low, so i thought of a 723 ang just adjust the voltage to 13.8.

The Vbe for the 2N3055 is quite high, it might be well over 1 V at
some larger current. Thus, the output voltage would be under 14 V and
with some emitter resistors to share the load between the transistors
even less than that.

Nominally, the 7815 can only supply 1 A and assuming worst case hFE
for the 2N3055 of 20 at 4 A, the output current would only be 20 A, so
five 2N3055 devices would nicely give 20 A. If more current is needed,
more series pass transistors are needed, but the 7815 is not capable
of supplying the required amount of base current, so a driver
transistor is required between the 7815 and the series pass 2N3055
transistors. With two Vbe drops, the output voltage would be 13 V or
less.

In many audio amplifiers, the filament was powered from a 6.3 V
winding with a grounded centre tap. If the centre tap was not
available, a potentiometer was connected across the filament winding
and the wiper was connected to ground and the wiper was adjusted for
minimum hum.

In RF applications, using bypass capacitors to ground at each tube is
a good idea.

Using a single floating 6.3V secondary winding with a potentiometer
connected across it and the wiper connected to the ground and adjusted
for minimum hum should be enough.

This kind of system works quite well when you have a single high
sensitivity input (such as in a radio receiver), but if you have
multiple sensitive inputs (as in audio mixing consoles) you would need
a separate filament winding for each input tube, in order to be able
to adjust the filament balance without compromises. In such situations
a DC filament system would be simpler to implement.

...or at least, say, 595-605Hz is the local oscillator tends to drift +/-5Hz over time, eh? Good enough.

With SSB, presumably you have the same 'problem' -- the entire voice signal is shifted in pitch by the difference between the LO and the real carrier. In fact, with SSB and direct conversion, how do you even decide you have the correct LO frequency? Just when people sound 'most natural?'

I don't know what the gain of the final is but I wonder if shielding
one of the two plug in coils (since they are not at right angles to each
other) would be a good idea..

I think my confusion stems from your choice of words :-) You equate
standing, walking, climbing, etc. in the open spaces amongst the coax lines,
cavities, etc. to being "in the diplexer" which I suppose in one sense is a
reasonable interpretation. I took your remark about being "in the diplexer"
to mean that you were actually inside one of the cavities during maintenance
or whenever it was not on-the-air ! You are correct, there is no absolutely
reason that you can't be in the immediate vicinity of all the components'
exteriors while it is in use [although you obviously would take great care
to avoid tripping over any cables powering fans, interlocks, reflectometers,
etc. as well as staying clear of any high temperature surfaces and generally
avoiding banging into or denting anything mechanical].

Probably a 3-1/8" coaxial line patch panel of some sort....either manually
operated or maybe motor driven with suitable interlocks.

>

Well, times have changed a bit since 9/11. But you are correct in
principle, especially if you make the proper initial contacts in the
Engineering Dept (or what little bit is left of it at most stations). And
being a licensed ham always helps :-)

Recently I've been thinking of building an RF power amplifier (for HF, as it happens), and I ran into the age-old problem where I'd love to have high efficiency but I need to be able to reproduce AM and SSB signals without distortion.

There are many ways to do this, but I find myself strangely attracted to this idea that just came to me. It seems so simple and obvious that it must be at least 50 years old, but I've never seen it before. Has anyone seen this technique before, and/or does anyone foresee any drawbacks to using it?

Note: the ASCII art drawing must be viewed with a fixed-width font, such as Courier, in order for it to look right.

FEEDBACK ENVELOPE RESTORATION FOR CLASS C (or D or E) FET RF AMPLIFIER

This feedback technique allows a class C (or D or E) FET RF amplifier to be used in some situations where a linear amplifier would normally be required. Even though the amplifier still distorts at radio frequencies, producing harmonics which must be filtered out, the AM envelope is correctly restored so that the entire functional block behaves as an efficient linear amplifier.

I worked for WACX CH-55 In Orlando. Their first transmitter was an
RCA TTU-25B, and was replaced with a Comark 130 KW UHF transmitter that
you had to change the coolant and antifreeze twice a year. Later, I
moved the TTU-25B to Destin Florida, rebuilt it, and moved it to CH 58.

I have used one of these to cut a hole in an aluminum panel. The panel
was clamped to a piece of pine and the table on my drill press. The drill
press was set to the lowest possible speed and the chuck was lowered slowly.
Took a while to cut and the cutter did get stuck a few times requiring
me to raise
the chuck and clear the problem. Did cut a nice hole, but required a
chissel
to break out the center and a file to clean up afterwards.

Except for high gain AF stages, a center tapped filament winding with the
center tap grounded should be ok. Otherwise a resistor of a few hundred to
a few thousand ohms from each side to ground (resistors of identical value).
Use of a pot is probably overkill, but if you have one in the junk box and
room to mount it ok.

The IO lines are 3.3volt compatible-- there is a pin for that. You can
get 8052 that run fine on 3.3 volts, or you can use resistors to divide down.
VHC logid (and others) can also translate down just fin.

I think RL Drake used copper chassis on their tube ham gear. Looked
real nice when new and shiny! I've build some equipment in home made
boxes made out of copper (you can get small pieces of sheet copper from
the hobby shop). Not cheap, but solders easy and makes a great ground
plane!

I built a cheap ps using a bunch of 2n3055's as pass transistors. (think
I had 5 or 6
of them in parallel). Each had a 0.1 ohm resistor in the emitter lead
to balance
out the current (or one might try to hog it all if the transistors
aren't well
matched). They well darlington connected to another 2n3055 which acted
as a driver (and helps increase the gain at high collector current).
Yet another
transistor was used to drive the driver (TO-5 si, probably a 2n3053 or

equal)
from the regulator IC. A large heat sink was used and I mounted surplus computer power supply fans on it to add cooling.

I used a heavy transformer and the input voltage to the pass regulator was about 15-16 volts for 13.6 out. Key here is that with a large transformer and
enough filter C the voltage won't droop on high current (guess that means it's well regulated without the regulator!) , and we don't ask the transistors to disapate too much power.

Course' such a supply is HEAVY, a switcher is much lighter, but a good switcher with low noise is hard to come by! (Not to mention problems of rf feed back!).

Yes, I know what you mean. I still have some pieces of sheet brass,
angles, and small tubes for RF work. I use to solder small brass boxes
together for shields when I built filters and RF pre amps. I was using
K&S Engineering materials sold at hobby shops, but the last hobby shop
in Ocala closed about four years ago. I am looking for a place to get
some deep drawn brass boxes and small tubing to build some DC blocks,
detectors, and dummy antennas to sell as alignment aids for older
radios.

3068. Measuring Velocity Factor w/ MFJ-259

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-30 04:38:34 UTC
From: Jason Dugas <kb5urq@hotmail.com>
Message-ID: <vq15emev53rvc8@corp.supernews.com>
Source record: 31535
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I'm interested in measuring the velocity factor of some coax I have (more of an exercise than necessity). In order to do this, the MFJ-259 Operations manual states that the "stub" to be measured should be attached with a 50-ohm noninductive resistor in series to that center conductor of the Antenna connector on the analyzer.

What would be a good way of making this connection? I've thought about it quite a bit; the best idea I've come up with so far is to have a small metal enclosure w/ two SO-239's mounted. The resistor would go from center conductor to center conductor of each SO-239. But this requires too many extra connections & lengths. Is there a better way to do this? Would love to see anyone else's experimental setup, particularly if there are pictures or details on the web.

Thanks & 73,

Jason

==========
Suggest you drill multiple holes (as close to each other as possible) with
a 1/8 inch drill all around a circle with a diameter of
3 13/16 inch .
Then knock out the circular bit of aluminium and file with a half round file
to 4 inch diameter.
It is a bit of a job but will give a good result.
Alternatively you can cut out the 4 inch circular bit with a jig saw ,using
methylated spirit as 'lubricant'.
Finish with a fine file or emery paper.

==========
Since no power is involved the non-inductive resistor can be very small .
If accuracy is a point ,get a 50 Ohms , 1% metal film resistor or select a
near 50 Ohms resistor from a batch of standard 5% resistors with an accurate
Ohm meter .
Cut the leads as short as possible but adequate for insertion and soldering
into the SO 239 coaxial socket.
You now know the minimum distance between de 2 SO 239 sockets and can make a
suitable enclosure from bits of scrap plain printed circuit board (in
Europe available at amateur radio fleamarkets and often sold by the
kilogramme)
With the enclosure completed and holes drilled for the SO 239 connectors
,fit one connector with the resistor soldered and subsequently fit the other
connector and solder it to the resistor.
The result is a resistor in between the 2 SO 239 connectors with hardly any
wire visible.
Finally finish the enclosure by soldering a cover of the same PCB material
or keep the cover removable by means of soldered nuts inside the enclosure
and matching screws.

========
For equipment NOT involving heavy components like large transformers ,you could consider making a chassis out of (scrap) double sided printed circuit board material , which is very easy to handle (drill ,cut ,solder) .
Components can be directly soldered to the chassis and RF screens of the same material can be readily added.
When screening sections ,feed-through capacitors can be easily soldered .
Over the years I bought cut-offs up to large sheets of double sided PCB (at amateur radio flea markets) , which can also be used to make front panels and small cabinets/ enclosures.

Seems to me the framing can't move- unlike a piece of sheet metal. I have many times used 2.5" bimetal hole saws to make openings for meters in 0.125 and 0.25" aluminum panels. The panels were in each case held to the mill (or drill press) table with at least 2 clamps. There is absolutely no way that one person could make that size hole with a hole saw w/o clamping. And forget a hand drill if you want the hole to look decent.

To the "cold" end of both main transformers, which are connected
together. You have to connect the primaries in such a way that the
"hot" ends of the secondary of each transformer is in the same phase,
thus the voltage of the hot end of each secondary is nearly equal and
the centre tapped choke will take care of the rest.

In three phase systems, connect the star points of the transformers
together, which is also used as a return for single phase loads. A
balancing CT choke is needed for each phase and also in this case you
have to observe the primary polarity when connecting the primaries.

Junkbox Surplus Parts for Sale
==========
I have about 100 excess pcs of 5.000 Mhz crystals. These are the miniture
crystals. Tiny round crystals with two wire leads, I think I've seen these
in watches.
The whole pile for $8.00

DPDT slide switches - these are .75 inch by .5 inch - 5 for a buck

I have surplus 50K 1 Turn linear taper pots, about 25 each. These
are chassis mount pots with the nut. About the size of a nickle, and
about 1/2 inch deep with a 1/4 inch shaft about 1/2 inch long.
5 for $5.00 including USA shipping.

9.8304 Mhz Crystals, 1/4 in tall - 20 for $5.00

27mH inductors with radial leads - 25 for $3.50

2.5/5.5mm Coaxial Power Jacks for PCB insertion or Manhattan install
10 for $2.50

L7805ACV - 5v Regulator, 1.5A, TO220 Format - 10 for $2.50
LM317T Adjust. Positive Voltage Regulator TO220. 10/$5.00

Caps - All new, old stock. No pulls.
==========
All listed caps now 50/$3 or 100/$5
==========
8pf NPO Ceramic - Loose
11pf NPO Ceramic - Loose
12pf NPO ceramics on tape
22pf Kemet Ceramic Caps, 200v, 10%
150pf ceramics, 100v, 10%

My stock of double sided epoxy board is a 4 ft by 4 ft sheet I bought at a hamfest for $20 or 25 IIRC. I have some smaller pieces left over from the past.

If you don't want to solder partitions or sides, you might do as I and buy a 10-ft length of extruded aluminum angle, 0.25 inches on a side. This way you can screw things together without worrying about overheating / delaminating the PC board. You can also take things apart if needed :-(

I'd be careful about using aluminum for this. You could set up a situation where over the years, the dissimilar metals would begin to react and cause all sorts of gremlins. I'd think you'd want to use copper or brass angle stock, which is also available, albeit more expensive...or plastic; or even wood. The plastic channel stock that is used to join masonite wall panels comes to mind. If you used nonconductive material, it would be easy to connect the chassis parts electrically with a few bits of copper braid or brackets.

I could be wrong about this, but judging by the debacle during the 70's where a lot of aluminum wiring got installed in a lot of homes--and later caused at least a few fires--I'd at least be cautious. I've also seen several places in my old houses where iron piping was screwed directly into brass fittings. I just dug up the faucet in my front yard, which a neighborhood kid had hit with a lawnmower. Water was bubbling up out of the ground. The shock from the mower was the final straw which crumbled the iron pipe at the threads where it screwed into the brass tee. When finally I got down to it, there was practically nothing of the threaded end left,

although the rest of the pipe was in good condition. I replaced it with a plastic nipple...didn't really need a second faucet in the front yard anyway.

That was mostly hype stirred up by Jeraldo Riviera. Back when he
was still caucasion.

The real problem with aluminum wiring was three fold. 1. For a
given current ration, the aluminum wire has to be bigger than
copper. 2. Special terminations (screw and or compression type)
marked CuAl shoud be used along with a gel like "No-Ox" to protect
the connection 3. Proper torque on the fastenings is manditory.

Given the special requirements and the attitude of most workers
that "I know what I'm doing" of course it was a disaster.

This is more the fault of the iron pipe. Not the bronze/brass
fittings. When you thread the end of a pipe, you remove the
galvanized coating. Exposed metal pipe = weak spot.

Yes, one can use a handheld drill with the circular hole cutters with
center bit, although a drill press will give a neater job.

The problem was with the fly-cutter style, which has a center drill
bit and an arm holding the single cutter. Small misalignments will
cause a lot of torque to fling the workpiece or the drill.

Aluminum wiring really made the news after the "Beverly Hills"
Nightclub (Just across the Ohio river from Cincinnati, in Soutgate,
Kentucky) burnt down, and it was completely wired with aluminum wire.
The fire was so hot that there was little left to determine the quality
of the the wiring job. The nightclub was built with very nice, real wood
paneling (3/4" thick), and the heat of the fire vaporized a lot of the
wire and fixtures.

It was a very nice place. One of the TV manufacturers used to have
their annual classes there. I think it was Admiral, but its been so long
I really don't remember.

Hi.

I'm trying to get my DEBEG 2000 HF receiver back into service, and suspect that I'll need one or two card extenders. I know of another SWL with one, and think he may be interested as well.

Does anyone have a lead on a fab shop that'll run off one or two sets of extenders for US$100 or so max? Specs on request, pointers to fab shops _very_ gratefully accepted.

The address below is valid and gets read regularly.

You can tin the edge of the PCB and avoid this for the most part.

3086. Direct conversion receivers for AM

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-30 21:22:01 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <bnrvdmghr1@news.oregonstate.edu>
Source record: 31403

I had this crazy idea to attempt to build a direct conversion receiver for regular old AM (i.e., two sidebands, carrier included). It eventually occurred to me, however, that there's the very significant problem of synchronizing the LO to the incoming RF carrier. In diagrams I've seen, normally a PLL is used at the IF frequency (455kHz being common for AM receivers, of course) to lock the two together. Is there anything comparable one can do with direct conversion? It seems that if your LO is sync'd with the incoming carrier, you'll have a very large DC component (the AM carrier!)... if not, however, you still might get some DC that's been aliased and while this will (should) always be less than the DC component when you're locked, it gives no indication of which way your LO needs to move to achieve lock.

So apparently what I'm really asking is... can one build a phase detector that works at DC? Or does an AM direct conversion receiver necessarily require an IF strip?

Thinking out loud,
---Joel Kolstad

That might be the case if every iron pipe also exhibited this effect. The
only place I've found it was when an iron pipe was mated with a brass
fitting. A similar situation occurred in my kitchen wall, where the faucets
(mounted on the wall) were connected to the brass elbows nailed to the studs
with a short iron pipe. The ends of both pipes were corroded to hell within
the brass. I had to dig the rotton bits of iron out of the brass threads
(not as difficult as it sounds, the iron was completely oxidised and
crumbling) without damaging the brass. Otherwise, I'd have to had opened up

the wall to replace the elbows. Just a few years later, when the kitchen was remodeled and a more conventional sink installed, the replacement pipes were already noticably corroded. Any time two dissimilar metals are placed in contact with each other, galvanic action occurs. Given a bit of moisture, corrosion occurs; thus the No-Ox paste for copper to aluminum terminals.

A Galvanic chart appears on this manufacturers website:
http://www.katonet.com/Techinfo/Newsletter/2000/may-jun-00.htm

Probably, but the object was to eliminate heating the copper board. Other coatings would work, as well. Zinc chromate primer is what they use in aircraft construction.

The hardware stores around here sell special unions, with insulated
threaded fittings, for mating iron/steel pipes to brass. I've
pondered whether these might be useful for making certain forms of
(non-DC-connected) copper-tubing J-pole antennas.

>50-ohm noninductive resistor

Hi Jason, I just looked at the manual for the 259 and the 259B and it did not mention a 50 ohm resistor in the velocity factor section. With both instruments you measure the electrical length of the coax and compare to the physical length to obtain velocity factor. It is a bit easier with a 259B using the "distance to fault" function. The coax can be open or shorted (far end) during measurement. No resistor needed as far as I can tell.

We used similar fittings when building water-cooled RF coils, used in
plasma deposition vacuum systems. Since the skin effect means that
most of the RF is transmitted on or near the outer surface anyway,
there was little loss compared to a solid copper rod. We could have a
complete plumbing circuit with an electrical discontinuity.

Happy trails,

Those are specifically mating up old iron piping with new copper.
For the prevention of galvanic action.

I jumped in at the "make them removable" part. Doing a bit of tinning
wouldn't really qualify as heating the board enough for the copper to
peel up.
Actually I think that would be preferable to "paint on" coatings that
might flake/chip around the screw holes in this case.
But we have now made a simple everyday PCB board box into a home project
that meets FAA specs.

This is a problem in general in direct conversion schemes: and this is the reason that "quadrature" detectors are made, with two mixing channels 90 degrees apart, so that the phasing is no longer a problem. (the sqrt of sum of squares of the signal out of the two channels (or "magnitude") is not sensitive to phase.)

Hmm... I went through the math, and indeed, this is the case!

But this then begs the question: Since the quadrature detector obtains the correct magnitude of the transmitted signal for ANY phase difference between the carrier and the LO, and if we model the phase difference as a function of time that slowly changes due to the fact that, in actuality, our LO isn't _quite_ the same frequency as the carrier, will the system still work? This almost seems too good to be true...

Thanks,

Of course, if you were demodulating DSB suppressed carrier and you injected the carrier at the wrong phase, you indeed would get the two sidebands going through constructive and destructive phases. If you're 90 degrees out with your LO, it looks a lot like narrowband FM, though very slightly different as I posted in the thread on SSB-FM. If you do the quadrature detector thing with DSB-suppressed carrier, then when one of the two is just the wrong phase (and you get no output from that one), the other will be just the right phase, and vice-versa. When it's in between, does it work out right to just sum the two? I suppose so, though it's worth going through the math to make sure. And of course, with quadrature mixers, you can combine the outputs with audio phase shifting to select just one of the two sidebands (or just CW signals on one side of the LO). In fact, the mixer LO inputs don't have to be exactly in quadrature: it's possible to apply a calibration to account for a phase error (and also an amplitude error, where the gain through one mixer path is slightly different from the gain through the other). That's all practical to do digitally...we do that sort of thing at 100 megasamples per second with some custom chips.

Cheers,
Tom

3099. Re: Direct conversion receivers for AM

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-10-31 07:46:58 UTC
From: k7itm@aol.com
Message-ID: <3200347.0310302346.4d8f4482@posting.google.com>
Source record: 31416

I guess this is further to the followup I just posted in another
thread!

Consider the quadrature mixers. If your LO is in phase with the
incoming carrier on one, as you say, there will be a high DC coming
out of that mixer. But out of the other mixer at that time, you'll
see zero DC. If you move the phase just a bit one way, the quadrature
detector output will go up; move it the other way and the quadrature
detector output will go down. So, if you appropriately filter that DC
signal, you in theory will be able to lock the phase of the LO. The
problem? You'll need to be darned sure your mixer is really balanced!
If you are receiving, let's say, a 10 microvolt carrier, then you
only get around +/-10uV of DC to work with, and if the mixer is
imbalanced enough with no signal at all into the RF input to give you
that much DC, you'll be in trouble trying to "see" the DC from the
small carrier.

But not all is lost. As noted in the other thread, you may be able to
combine the outputs of the two quadrature detectors and use that.
What you won't get is rejection of noise that's in quadrature with the
transmitted carrier, which is an advantage of synchronous detection
(properly phase locked).

I've thought that if you have two broadcast stations whose carriers
are phase locked, it should be possible to find an antenna location
for receiving that puts the two carriers 90 degrees out of phase, at
the receiver, and you could listen to the two stations independently.
I have a spectrum analyzer that can resolve (very) small fractions of
a Hz at RF, and it's interesting to put a few feet of wire on it as an
antenna and set it up on a standard MW broadcast frequency with a 10Hz
span. Even in the presence of a strong local carrier, you can see
typically several other carriers in there, at least during nighttime
propagation.

Cheers,
Tom

Gary, the manual indicates to 'Set up the line to measure 1/4 wave stubs as
in the section on "Testing and Tuning Stubs"'... In that section, it
requires a 50-ohm resistor in series to the center conductor. Perhaps, the
resistor isn't needed to measure VF? This is really a poorly written
manual-- while it acknowledges possibilities, it really isn't clear in its
procedures :-/

Let me know what you think. Maybe you're right and the resistor isn't
needed for VF.

Thanks,

Jason

This makes sense to me if you stick, e.g., (1+s(t)) -- where s(t) has not DC component -- on your I modulator and, say, t(t) -- where t(t) has no DC component -- on your Q modulator. DC filtering the I output, then, should directly provide cos(phi) -- where phi is the phase offset phase the RF and LO carriers -- and DC filtering the Q output provides sin(phi) (which is probably the more useful signal for the sake of feedback). (For regular AM transmissions, t(t)=0... I'm just thinking ahead to AM stereo here.)

> The
> problem? You'll need to be darned sure your mixer is really balanced!

A pair of NE602s sitting side by side doesn't really cut it? :-) I was actually thinking that the solution here is that you let the AGC run off of the quadrature detector output (sqrt(s(t)^2+t(t)^2), assuming you removed DC from both channels) and only when the signal strength is above a certain level do you allow the phase locking circuitry to kick in and attempt to null out the phase differences.

> I've thought that if you have two broadcast stations whose carriers

Good point!

Side note: In looking up quadrature detectors, I was amused to find that someone has a patent on using one for standard commercial AM band reception. Amazing...

For more on LO vs. RF carrier phasing differences, I'm going to follow up to the other thread.

Date: 2003-10-31 15:47:42 UTC
From: Joel Kolstad <JKolstad71HatesSpam@Yahoo.Com>
Message-ID: <bnu07o$5fs$1@news.oregonstate.edu>
Source record: 31421

With all this discussion of phasing fun... could someone answer the following question for me?

Say I'm transmitting binaural audio, with I being L and Q being R. I receive this signal and generate my own I' and Q' outputs. However, if the RF carrier and my LO have a phase difference, the entire IQ (phasor) diagram is rotated by that difference and, e.g., a 90 degree difference will result in the left and right channels I receive being swapped.

How do IQ-binaural receivers recover a phase lock to present this?

> If you do the quadrature detector thing with DSB-suppressed carrier,

> make sure.

I went through the math and you end up with the magnitude of the original signal. What's unclear to me is how to recover the phase offset between your signal and the original -- although adding a DC component (or some other unique frequency component) to either I or Q (or placed at some strategic angle between them) would allow you to synchronize the phases.

Have any suggestions for a nice simple mixer (ala the NE602) that retains both the I and Q signals at the output?

Of course: this is how synchronous AM detection works.
They generate a clean, in-phase carrier and use that to
demodulate the incoming signal.

To make a direct conversion receiver on similar principles
would require a frequency-agile PLL. You could use a Costas
loop, for example. If I was to do it today I'd convert
to I/Q baseband and do the rest in DSP.

The trick of phase locking to the IF definitely works. I believe it's called synchronous detection. One trick that might allow for simpler hardware would be to use a 5 kHz IF. (You'd need to use filtering or phase cancellation to get rid of the unwanted product on the other side of the desired signal.)

It should even be possible to use quadrature detection with the LO off by 5 kHz, then feed both the I and Q channels into a DSP and "phase lock" to the IF frequency in software.

A coworker of mine told me about still another DSP trick, where you tune as close as you can to the carrier, but of course you're a few hertz off. Looking at an I/Q diagram, the slightly off-frequency AM signal will look like a rotating vector. So long as there isn't a lot of noise, the DSP can keep track of the polarity as the phase rotates, and recover the AM as the magnitude of the vector.

Double Cotton-Covered ("D.C.C.") Do they still make this stuff? I would like to obtain some for winding RF coils for homebrew radio receivers. Anybody know of a supplier or maybe have some on hand?

thanks,

Dave

LOL...but, naah...the original idea would work with just a quick squirt of
z.c. primer (from a can) on the inside of the aluminum angle stock, I
guess...not that much trouble, in order to avoid further troubles down the
line. If the assembly never got wet--or stored/used in a humid
environment--those problems would likely never show up. OTOH, probably best
to avoid problems in the first place.

Both belden and Alpha made it, so I would start with Newark, Allied, or another large OEM distributor. Also, see if there is a motor rewinding shop in your area that might use it on small motors. You might pick up a partial spool at a decent price.

For standard broadcast, don't they always put L+R on I and L-R on Q,
so standard receivers get L+R? All this is not my forte; I know only
enough to be dangerous with it. But I assume that in any transmission
standard, there is something transmitted that lets you recover the
right phase at the receiver. If you're sending symbols, presumably
there can be some symbol you transmit periodically to insure things
stay synched, a complex version of the old RS-232 start and stop bits
if you will. For analog signals, you can transmit some sort of pilot
tone, perhaps the carrier itself, which of course must be done for
compatible AM anyway.

One easy way is with a "Tayloe mixer" -- you should be able to find
info on that on the web, but it's basically just a commutating switch
that switches the signal (through its source resistance) among four
different capacitors. The I and Q outputs are V(C1)-V(C3) and
V(C2)-v(C4) respectively. It must be driven with a "LO" at four times

the detected frequency: that is, the switch must rotate through all four positions in one cycle of what would normally be considered the LO frequency. If you use care in its construction, you should be able to get very good balance. The size of the capacitors determines the bandwidth. There are commercial quadrature active mixers, too, but they typically cover a modest frequency range in the VHF region or higher.

Cheers,
Tom

And this comes from someone who I could swear posted not long ago a
table that had velocity factors for solid polyethylene cable that were
significantly different from this magic number?

But even if we just limit ourselves to HF and above, there's a
problem: most "solid poly" cable I've encountered has small gas
bubbles in the dielectric, and the v.f. does not measure exactly
0.665. Most of the time, the difference doesn't matter, but sometimes
it does, and then it's not safe to assume it's 0.665. And of course a
lot of cable these days uses foam dielectric, which can be noticably
different from batch to batch.

They may well -- I'm not sure which 'standard' we're talking about here (there seem to be several out there...). :-) But note that with L+R on I and L-R on Q, you only get L+R if you manage to synchronize with the phase (the original problem)! If you use a quadrature detector and extract the magnitude, you of course get sqrt(L^2+R^2) -- good, but not exactly L+R either. The Motorola C-QUAM AM stereo system forces the magnitude of the I-Q phasor to be L+R, which makes it compatible with both envelope detectors and quadrature detectors. (I probably sound like a Motorola sales guy these day... I just think it's clever and the end goal here is to build a direct conversion receiver to decode it...)

> But I assume that in any transmission
> standard, there is something transmitted that lets you recover the
> right phase at the receiver.

For AM, it would appear that the carrier itself is what people use for that purpose.

If it very clear to me now why TV transmission need to send the colorburst sequence these days -- otherwise they'd have no way to synchronize the chroma decoder, which is taking in a DSB-SC modulated in both I and Q.

> One easy way is with a "Tayloe mixer" -- you should be able to find
> info on that on the web, but it's basically just a commutating switch
> that switches the signal (through its source resistance) among four

I was just thinking of doing something like this -- from a square wave, get a 4 bit shift register (that always has one output active) and feed the outputs to a 4066 such that I sample the 'I' channel during, say, clocks #1 and #4 and the 'Q' channel during clocks #1 and #2. Add some filtering and -- presto chango! -- we've got I and Q.

Thanks for all the help -- this just might end up working after all.

==========

Your para. 1. You can swear till you're appoplectic black and blue in the face - it wasn't me. I'm not THAT stupid. So who was it then?

Your para. 2. If there are little bubbles in it, it is not solid. If it is foamed, it is not solid.

Just to add a little more useless information, did you know the stuff also varies with pressure and temperature as at the bottoms of the oceans? Also, under pressure, water disassociates and hydrogen slowly diffuses through it. Rodents seem to take a fancy to it.

Velocity factor = (Permittivity)^(- 1/2). Permittivity of polyethylene = 2.26 but it does vary slighty from one book to the next.

Reg.

I've used this kind on metal and wood in a drill press with the work
clamped.
I really think this kind of cutter was made to cut wood judging on how
it worked.
In any case I wouldn't use it on steel, only soft metals such as copper
or aluminum, and
then with a wood backing board.

I tend to agree, based on past experiences in finding VP of lots of different RF-video cables. That includes some "economy" type cables where the dielectric looked like polyethylene but a burn-and-sniff test proved it was some other polymer.

There's some good formulas for finding out the VP of coax in the May, 1978, issue of HAM RADIO magazine. The title is "Antenna Bridge Calculations" with my byline and was for folks using a calibrated Noise Bridge and had access to an HP pocket calculator. A Noise Bridge nulls for admittance but this will convert to impedance with a complex inversion...much handier on the newer HP 32 SII calculator.

The formulas in the May '78 issue of HR will work with the MFJ analyzer's impedance read-out values.

I don't think that Belden or Alpha has made that kind of wire for at
least 2 decades. Got both of their big factory catalogs here and
all I find is "magnet wire" in either light or heavy (two coat) plastic
insulation. My new Mouser catalog has only part of two pages
with "magnet wire," both being the equivalent to old "enamel
covered coil wire." Might try the search engine at Digi-Key, but I
doubt there will be any success.

Last I was at a place that rewound electric motors was 8 years
ago and they had only heavy plastic covered "magnet wire."

The old cotton-coverd coil wire was okay 4 to 5 decades ago but
doesn't offer much for coil building except for the cotton insulation
being excellent to absorb shellac that will dry and hold everything
together very nicely. Actually, back in the old days, a ceresin wax
application was more likely to be applied...dried quicker and moved
the product through production faster. I happen to like McCloskey
"Gym-Seal" floor varnish to coat home-wound inductors, solenoidal
to toroidal...it's all petroleum-based, not a polyurethane, and doesn't
come loose in high moisture environments like some polyurethanes.
"Gym-Seal" seems to stick to polyester and polyamide magnet
wire coatings very well.

There's a slight difference in distributed capacity between DCC and
enameled wire, DCC usually being slightly less (any coating applied
over it will change that to not less). Not enough distributed capacity
to worry about in my estimation.

There's a slight difference in inductance for a given coil form dimension
between DCC and enamel-covered, the DCC having slightly less for
the same number of turns. Again, not enough to worry about.

>How do IQ-binaural receivers recover a phase lock to present this?

You are using an example of separation of conventional AM
sidebands. Phase synchronization to the carrier can be done
separately or by using parts of the multi-mixer I-Q circuitry.
Phase synchronization is not absolutely necessary for listening
and still hearing separate sidebands.

Relative phase in mixers is NOT disturbed. (basic fact)

Single-sideband phasing systems use at least two mixers, the
LO of one in quadrature (90 degrees) phase with the other LO.
Since the LO frequency is the same, the two mixers' output will
have a relative phase difference of 90 degrees.

In addition to that, the mixer outputs are put through an audio-
frequency-range wideband phasing network. The Gingell 4-phase
network is ideal for this (it works fine with just two phase inputs).
With the Yoshida value optimization, the Gingell network can be
made with excellent constant-relative-phase-quadrature over a
broad audio frequency range without using precision tolerance parts.

The "trick" now is to linearly combine two of the four audio phases
such that the TOTAL relative phase shift is 0 degrees (or very nearly
so). With the LO having a relative phase differential of 90 degrees
the audio output of the mixers will have a differential phase of 90
degrees. Since the audio polyphase network provides additional
90 degrees relative phase difference, the total is 180 degrees...or 0
degrees if an inverting unity gain amplifier is used.

So, what happens if the LO isn't "locked" to the incoming carrier?
Actually, very little. If the 2 LOs remain in quadrature phase realation-
ship, the two mixer output relative phase relationships are STILL in
quadrature. The only thing that has changed is the slight frequency

difference in the mixer outputs relative to the original modulation frequency. This has no effect on any broadband audio phasing network following the mixer outputs...those maintain the additional quadrature relative phase and linear addition and subtraction will be the same. Unwanted sideband AND carrier suppression in demodulation will be essentially unaffected.

In going back through messages after a short absence, I detect some worry about a slow "beat" effect if the LO isn't synchronized. That's not a real worry if you've gone through the full expansion of the basic AM equation and shifted the whole series in phase by 90 degrees, then did a linear comparison with the same series unshifted in phase, then taking the TWO audio frequency components from the series and did a linear addition or subtraction with an additional 90 degree relative difference.

Synchronization-to-the-carrier-frequency-and-phase is necessary only with conventional AM and the audio circuitry being broadband all the way down to DC. There are several ways to make the DC component represented by the carrier mixed down to baseband either disappear or reduce greatly in value. Hint: Using the full series expansion, use a small phase shift error and note the comparisons of all series components, including the carrier.

With SSB, there's no real worry since the transmitting end carriers are already reduced reduced in amplitude. If the LO isn't quite in sync or even not on-frequency, all that will be noticed is the slight change in demodulated audio frequency relative to original frequency. The amount of rejection of RF in the unwanted side of the carrier will vary by the error of exact LO quadrature and the error of the phasing network quadrature. On conventional AM, those errors are the same as the isolation between sideband modulation content. If the AM has left ear content on lower sideband and right ear content on upper, that isolation is the same as "left-ear v. right-ear separation of stereo."

>Have any suggestions for a nice simple mixer (ala the NE602) that retains
>both the I and Q signals at the output?

"A" mixer, no. You must use at least two to get an In-phase and Quadrature output. The Tayloe detector has several advantages. First, the CMOS switch can be driven with 4 phases, not just 2, and the equivalent conversion transconductance is far higher than any passive mixer; mixer noise is also reduced relative to active mixers due to the nature of the CMOS switch structure. With four phases in the output, all at 90 degree multiples, it fits the Gingell-Yoshida polyphase network just dandy such that quadrature errors from network components are greatly diminished.

The original Gingell polyphase network as described by Peter Martinez* in RSGB's Radio Communication magazine in 1973 had only 0 and 180 degree audio phase differences at the input. The network outputs were still at 90 degree multiples over a wide audio bandwidth. That bandwidth will increase and with less error when

inputs are already at four phases of relative quadrature.

The only disadvantage of the Tayloe mixer is the need to use a 4x frequency master LO if the four phases are derived digitally for broad tuning range.

*G3PLX, the same that inovated PSK31 some years later.

Old radios used 5v tubes off 6v batteries and a rheostat to control filament voltage. I was talking about using resistors to create a center tap for a transformer
without one. While this was used to power directly heated tubes off ac, it could be
used as a hum balance for heater cathode types.

The last cotton covered wire I used was around 1970. I bought a large spool surplus to make a bunch of heavy duty degaussing coils for early color TV sets. 300 turns of 17 AWG DCC, double enameled wire that was surplused by Picker X-ray, and sold to Mendelson's, in Dayton Ohio. They had hundreds of partial spools, and I think they still had some in 1987, (The last time I was at their store in Dayton, Ohio) It was still listed in the last belden and Alpha catalogs I received, but I would have to dig them out to get the dates.

Tell me about it!!

Back in the 1950s I helped restore a pipe organ
that was removed from a movie theater. The
guy removing it just wanted to scrap the pipes for
their metal, but died shortly after he started the
process. A friend got it free, just for getting it
out of there. This was a four manual Wurlitzer.

All the cable bundles had been cut with an axe!!

It took a whole summer to buzz out *thousands*
of wires and get two ranks of pipes playing on
two manuals.

Dave -

Contrary to what has been posted, cotton cloth braiding machines still
exist --
even at the big wire manufacturers -- however today they are usually used
for special orders.

Now, Odis W. LeVrier OWNS a cloth braider and makes beautiful replacement
cloth wire for
antique telephones (cloth covered tinsel, cloth covered line cords, desk set
cords) Photos are on
his web page. Please contact Odis directly for your special requests or
orders - he may be able to accommodate!
http://www.houseoftelephones.com/index.htm

Other "urban legend" - No one is fixing classic WE, AE, SC telephones
anymore - WRONG
Steve Hilsz just fixed my Dad's old Northern Electric desk phone - now worth
over $ 200
in collectable/antique telephone market ! You should see what the original
candlesticks sell for !!

> work ok, Im not sure about paralleling DC supplies ?

It should work fine, but your DC output voltage will end
up higher with the addition of the required filter cap.
Voltage across the cap will be about 26 volts, no load.
Parallel the output of the bridges, install a big filter
cap, and run the resultant voltage to a voltage regulator.
Do not regulate prior to paralleling the supplies!

Your regulator can be an LM317 or 7812, with pass
transistors in a "collector wraparound" configuration.
I'll describe such configuration below, using a 7812.
You can parallel a number of pass transistors - I'd use 4
2N3055's (2N3055's because I have a lot of them) with
a .1 ohm 5W resistor in each emitter leg. You can use a
7812 with 2 or 3 diodes in the ground leg between the leg
and ground, connect the output of the 7812 to the parallel
xsistors collectors. The base of the transistor goes to
the input pin of the 7812. From there, a 2 ohm 1 watt
resistor connects to the + side of the cap where the emitter
resistors also connect. If you look at the 7812 datasheet
application notes, you will find an example of the circuit
there with a single pass transistor (and thus no emitter
resistors) and no diodes in the ground leg.
http://www.national.com/ds/LM/LM340.pdf

The pass transistors have to handle about 205 watts
(12.8 volts * 16 amps) so you need a good heatsink
for them. You also need to heatsink the 7812.

The LM317 circuit is essentially the same. Look at
its datasheet. You won't need the 2 diodes in the
ground leg, but you will need to add a couple of
resistors.

As far as I can see, these web sites are offering cloth-covered stranded wire, such as would be used for hook-ups under chassis and such. I'm looking for "D.C.C." wire such as was used for winding coils. I guess it would be considered "magnet wire" ?

I think Charles Days in So. Dartmouth, Mass also makes the wire. (He collects old textile machinery) He used to be quite regular here but I haven't seen him posting in quite a while. He was juggling email addresses towards the end and I recall the most recent to be shortNOSPAMcircuit@att.bi.com. His mailing address is on qrz.com-ham call WA1JFD.

"Magnet wire" is not fabric-insulated. Instead, it has a coating of
varnish, formvar, etc. It will work well for winding coils, but it
won't look like DCC.

To the best of my knowledge, the last "high-volume" use of DCC wire was making cables for pipe organs. The pipe organ guys used it because you could treat it as pushback wire, and that saved time due to the many thousands of connections and conductors a typical pipe organ contains. The last manufacturer was, I believe, the Philadelphia Insulated Wire Company.

This stuff was getting very hard to find around 1980, I have no real reason to suspect that it is made at all any more. But, I am sure that there is a lot of it laying around. I just don't have any!

<< Of course: this is how synchronous AM detection works.
They generate a clean, in-phase carrier and use that to
demodulate the incoming signal. >>

Laura & Joel-

I was just thinking that. I recall there used to be (may still be) a shortwave broadcast station just above the 15 Meter band, that broadcasted with a partly suppressed carrier. Apparently the SWL community has access to equipment with Synchronous detection capability.

Listening to it on an AM receiver, it could be understood but was distorted. It was easy to tune it on a Ham transceiver as if it was SSB, but tuning was critical for music to sound good.

Addressing the original question about direct conversion, what if you used a temperature compensated oscillator with a phase-locked-loop? If the assumption could be made that the broadcast station will not drift, then you could tune each station dead on with an RIT-like adjustment of the oscillator.

Wanted: A 23cms preamplifier, prefer an RF switched type. Well made home brew example is fine, so long as it works properly!

Also wanted: A linear amplifier for 23cms, approximately 1.5 Watts input, minimum of 15 Watts output required. Again, good home brew example is fine.

Can collect (located near Reading, Berkshire,U.K.) or will pay postage. I have a PayPal account available to speed things up.

Please e-mail me if you can help.

Thanks,
Al, G4VSQ

Just curious. I got some spools from a friend, but don't really know
when it is an advantage to use the cotton covered wire instead of the
normal enamelled copper wire. Used it for some VLF purposes to make
lower self capacitance of coils, but appying single strand wire was
just to use what was available instead of multistranded wire

How sure are you of this? I don't recall seeing it in the Belden
catalog, and when I built a Tesla coil in the 50s a Belden engineer
helped me (Belden is still located in the town where I grew up, a
GREAT field trip, BTW.) The instructions we were following called for
DCC magnet wire, but we couldn't buy any even then. The Belden
engineer even inquired to see if their prototype shop could whip up a
batch just for us, but they didn't have any way to do it by then.

I suspect that it's been 50 years since anyone in the US has made SCC,
DCC, SSC, or DSC wire.

Everyone remember those?

As I mentioned in another post, I was using good quantities of it (on a "serious hobby" basis), in 22 - 26 awg until the late 1970's. Curiously, until that time you could also buy DCC cable, 20 - 26 awg, conductors were bundled in groups of 11 and the whole assembly was enclosed in PVC and impregnated with paraffin; this cable again being a specialty item for the pipe organ market.

I also remember silk covered wire, somewhere around here I have a small roll of #40 silk covered. I always loved those cute little wooden rolls that old magnet wire came on, kind of like a giant roll of thread. I am trying to remember some of the manufacturers, maybe I'll look around and see if I still have an old spool laying around with a label on it.

I am interested in expanding my freeband hobby but do not wish to take t
he General class hammie test until the code is dropped. My question is d
oes anyone know when the code will be dropped and how long woould I need
to wait until the written General test is simplified such as the Tech t
est is now?

Plase email me a WAV of morse code so I can hear what it sounded like wh
en the old hammies used it.

I have a 1959 metal spool of #20 AWG wire which is at least single cotton covered, but I don't think the innermost covering is cotton. Unwinding the outer green/white threads shows something else underneath, but it doesn't unwind; it has to be scraped off, but it is NOT enamel. The spool is 4 inches wide and the wire is about 1.75 inches thick; I have no idea of the total length, but the total weight is 6+ pounds.

If you think it might serve your purposes, make me an offer. Don't forget to include shipping (plus something to reimburse me for storing it for 44 years!-)

You've never worked on ground support test equipment in the
aerospace industry then. 3" diameter bundles of cables that
are all color coded white. 24 AWG teflon covered.
And that was on the "simple" ones.

You may think it says this:
MFJ-resistor-coax_center_conductor--
|
---------coax_shield------------

But maybe it means this:

MFJ----------------coax_center_conductor-resistor-
|
----------------coax_shield--------------------

I don't know what the MFJ documentation says - but if
they want a 50 ohm resistor in series from the center
conductor and the shield, put it at the far end of the
length of coax you are testing. Connect it as shown in
the bottom diagram by soldering the resistor directly
across the center conductor and shield at the far end.

The way I do it is to cut a physical 1/2 wavelength
coax for the frequency, install a pl259 on one end and
connect it to the MFJ. I install a 51 ohm resistor at
the far end of the coax. When that resistor is 1/2
wave away *electrically*, it's impedance will appear
across the PL259 plugged into the MFJ. You need to
shorten the coax by snipping off some of the length
at the far end, then reinstalling the resistor.
When you have the thing at an electrical 1/2 wave
you'll get Z=50 at the MFJ. Your VF is the length
of that piece of coax divides by the original length.

Maybe the MFJ documents a better way - I dunno - but
I've used my way successfully.

TNX, seems to be the only info available. Could check at the import
agent.
If they stand 55V it means that they will run safe with unstabilized
28V swinging up to 32V under no-load, and the 19" standard-48V to +24V
stabilized powersupplies don't need to fill up my shack, the problem
is only to find transformers suitable for so many 200W Power
amplifiers as I have room for, hi

The equipment is shown on http://home.online.no/~la8ak/d24.htm but
text is in Norwegian because it is limited interest and it is an offer
for the amateur radio groups to collect the hundreds of paging
transmitters if they can take an initiative, many can't, hi

The future of the code is still in limbo, and could be resolved in several months, or years. As far as the written, it is about as easy now, as it ever has been.

Jan -

The photos you supplied show very nice units. This approach is used in many
of the
solid-state designs for commercial FM (88 - 108 MHz) and VHF television
broadcast transmitters.

You may wish to correspond with JA0TJU. He had several designs based upon
this
bi-polar transistor. Another possibility is to look at W9NUP work with
combining in his 1 kW VHF / 2-meter amplifiers

I always prefer a regulated supply - wide voltage swings introduce other
problems.

Almost all RF transistors follow the following voltage "tiers" (with primary
usage/market)

12 / 13.8 VDC - automobile, portable usage

24 / 28 VDC - aircraft, military usage

48 / 50 VDC - telephone / telecommunications usage

Some prefer the 48 / 50 VDC devices - since it lowers overall current
(amperage) and allow usage of
240 to 120 volt step down transformers -- for stepping down 120 volt to 60
volt in the power
supply circuit.

3156. Getting A Signal in the Basement? (antenna lead-in for AM BC and/or shortwave)

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-02 19:42:20 UTC
From: David Forsyth <foda01@ncx.com>
Message-ID: <vqan3crrl44ffa@corp.supernews.com>
Source record: 31323
Cross-posted to: rec.radio.amateur.homebrew,rec.antiques.radio+phono

In the interest of my recent tinkerings with radios (both antique and homebrew), I have put up an 80 foot straight wire antenna above the house. It sits about 35 feet up from, and horizontal to, the ground. I am using a lead in from one end made of insulated stranded copper wire (basically old speaker cable, about 18 guage I think). Right now, the lead-in wire comes down from the end of the antenna closest to the sun porch, and in through the storm window via a well-insulated bushing. Due to the location of this lead-in, this is the spot wherre I have been doing most of the tinkering with the radios. I also have a copper pipe ground rod in a nearby location so as to have as short a path to ground as possible.) It seems to work OK for now but I would ideally like to run the lead-in into my basement where my workshop is. I read somewhere (I think it might have been in reference to crystal sets) that you can use coax for an AM lead-in. Would this be better for a longer/more convoluted lead-in? Would I use the braded shield as the ground connection or would I run a separate ground back to my copper rod outside? What type of coax would be best for this sort of thing? I am interested in receiving both broadcast and shortwave. Any info on this matter would be most appreciated.

thanks in advance,

Dave

How does the 259 differ from the 259B? Does the 259 have a distance
to fault mode?

I ask because the instructions for the 'B say that coax lines must be
open or *shorted*. Anything in between is verbotten.

With the 'B you use the "distance to fault" mode to figure
out the electrical length of the line then devide by the
physical length to caluclate the velocity factor.

Not necessarily. If you need shielding for noise purposes that might be worthwhile but apart from that there's no advantage over just a single wire. The radios you're typically working on have high impedance inputs.

In a random-wire installation, the total length of the wire IS the antenna. There is no lead-in per se. By using a shielded cable you are effectively shielding that portion of your antenna. I think you might find it won't work as well on BCB with the shield grounded and you would have to lift that at the radio end negating having it there in the first place.

On shortwave freqs the loss of the cable in a mismatched state such as feeding a random wire (or an old hi-z radio) may also work against you.

I'd go with the plain wire unless there is a noise problem that is being picked up by the vertical portion of the antenna.

My 2c.

-Bill

Being a smarter than average bear (my own opinion of course :~>) I
figured I'd use coax to bring my long wire antenna into the house, and
I'd ground the shield.

Didn't work very well.

Now I'm just using plain wires for each of the antenna and ground and it
works very well. I'd say that my antenna outside the house is about
10-15' off the ground and runs for about 100' in a 50' x 50' "L" shape.

If the antenna is the typical end-fed wire then the impedance will be very high. Most AM radios have a high impedance input designed to match a random wire like that. If you use coax, the capacitance of the coax (center conductor to shield) will essentially short most of the signal to ground and little will get to the receiver. If you've ever opened up the coax used on car radios you'll find that it is a special high impedance coax. A small wire fits loosly thru an insulated tube with the shield around the outside. This keeps a relatively large spacing between the center conductor and the shield in order to minimize capacitance.

Thanks for all who responded thus far (and sorry to be such a wellspring of newbie questons).

Yes, I must confess that there is no lightning arrestor installed as of yet! I was aware that one should install such a device at the time I put up the antenna, but I didn't have one handy, nor did I feel the need to invest in one. I was thinking that in the late fall/winter we really don't get any lightning here (north-east PA) and therefore I wouldn't really need a lightning arrestor until the Spring. I'm sure I'm probably wrong on this, though, as it was mainly a product of my Scots heritage getting the best of me.

I guess it would be helpful to include some more specifics about what radios Im trying to feed with this antenna. Thus far, I have accumulated an Atwater Kent "big box" Model 20, an Atwater Kent 55-C (chassis only), an RCA Radiola 18, and a homebrew regen. This is my latest project.

It uses a '36 screen grid tube as detector and a 6F8G as dual-stage audio driving a loudspeaker through an overly large Hammond OPT. So far I've only wound a coil for BC band and this thing works amazingly well. I plan on making some smaller coils for short wave (hopefully the solar storm stuff wont be long in staying).

I also have future plans for a Grigsby-Grunow that was given to me to fix up, but it's on the distant horizon as of yet.

So far nobody has complained about the large pile of radio-related crap in the sun porch, but Im sure it's a matter of time. I will probably have to route the antenna lead-in through a wall or two and around some bends and twists to get it into the workshop in the basement. I guess I was assuming I should use coax for this, but apparently not, from what everyone here is saying. I'm not as concerned about noise as I am about possible signal loss. Is this something to even be concerned about with a plain old insulated stranded wire lead-in routed through walls and such?

I'm still new at this RF stuff (being a relatively recent convert from the realm of "AF"), so please bear with me, and thanks for all the helpful tips and suggestions!

Dave

Bob, is this something I could possibly be able to use in this application? Where does one find such high-impedance coax? As an alternative, would it be possible to put an active device up near the antenna that would act as a buffer to feed a low-impedance line?

I will probably be dropped soon, but the FCC has to go through standard
procedures with all the pending petitions. The international requirement
was dropped on July 5th, so by next July it should probably be gone in the
US.

Hi,
David wrote:

Sounds familiar. Actually a lighting arrestor isn't worth much,
and I'd suggest a large knife switch directly between the lead-in and
ground.

Your present antenna is ideal for broadcast reception since, as has
been mentioned, most antique radios were designed with this sort of
antenna in mind. Extending the lead-in to the basement will simply
make it work better. The vertical part of the lead-in catches most of
the signal. Keep it as far from power lines and noise sources as
possible. If your ground is now farther away, you may lose some
efficiency; my ground is a driven well in the basement.

On short wave, things are different. I've used my inverted-L for
short wave too, but never compared it directly against another
antenna.

Cheers, Alan

The trick in this recommendation is that the car radio feedline is a
specific length (a few feet)and its capacitance is taken into account.

The MFJ-259 does not have a "distance to fault" mode. It has an "SWR" meter
and a "Resistance" meter.

It's quite accurate figure, but the cables are not so accurate.
Remember trying to make two RG213/U halfwave stubs for 100MHz, and was
surprised to learn that the 'halfwave' length varied about an inch

Suppose it wasn't only for the bubbles...

I believe DCC is actually what was used in the early days for what we today call "magnet wire." I'm not old enough to be sure of this, but my impression is that varnished magnet wire replaced SCC, DCC, SSC & DSC at some point. No doubt this conversion took place over some period of time.

I would draw a distinction between DCC, etc. and "fabric covered" wire. I believe the DCC, etc. was just a simple wrap of fibers meant to take up a minimum amount of space while still allowing close-wound coil turns to be insulated from each other, while fabric covered wire was covered with fibers which were actually woven together making it much more durable. Fabric covered wire was more likely to be used as hook-up wire, rather than coils.

Others on this list can probably pin this down better.

Do yourself a favor: at the end of your antenna (inside
the house) install a neon bulb and a 100K resistor in
series, connected between the antenna and ground.
Then, on a windy day, go watch the bulb.

You can make your own static discharge unit:

```
-----------\ /--------------
Copper \ / Copper
Strip / \ Strip
-----+-----/ \-----+--------
| |
+---/\/\/\/-----+
100K
```

The points on the copper strips need to be sharp, not
blunt, at the gap.

Wire one strip to ground with #10 or larger copper wire,
and the other strip to the antenna. Set the gap between
the copper strips as narrow as you can. Solder a 100K
resistor across the copper strips.

Hi,

There is no simple answer to your problem as the impedances
and frequency range involved are too great. However, as you are
not intending to use the antenna to transmit with, take a look at
this site and do a search on "LONG WIRE BALUN".

http://www.maplin.co.uk/

If you are in the U.S. I am sure that there will be an
equivalent item around somewhere. It is even possible that there
is a design for one of these out on the net.

The device is mis-named really and should be called something
like an UNUN. Of course it is a kludge but what the hell as it
should be better than a single wire or coax feed from your
basement.

Cheers - Joe, G3LLV

After doing a lot of reading on the web about long wires, short wires, inverted L's, impedance matching, baluns, ununs, onions, fundip, and who knows what else...

I was thinking (run for cover please)

Couldn't one simply use a small active device to buffer the straight wire antenna at the end where it tethers to Ye Olde Oak tree or whatever it's tied to? I was thinking you could even make it powered with a small gel cell or something and a solar cell to power it. Some sort of wide-band amplifier that would have a suitably high input impedance to accomodate the higher and varying impedance of the wire over the desired frequency range, and yet having a fixed 75 or 50 ohm output impedance to drive the coax that runs back to the house. Then you could use a transformer in the house at the receiver if it's the type that wants to be fed from a high-impedance. I would think this would get around the problem of an impedance matching transformer mismatching the antenna on frequncies where the antenna impedance drops significantly. Also it could provide perhaps some minimal gain to boot. Some of those commercial impedance matching transformers sell for over $50 US. So I would think a small buffer amp might not be too cost-ineffective.

Dave

3175. Switched reactances in VCO

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-03 12:49:15 UTC
From: alazos@in.gr
Message-ID: <347b6e9c.0311030449.5c1dd138@posting.google.com>
Source record: 31342

In the book "Introduction to Radio Frequency Design" of W7ZOI and in the section 7.9 "Voltage Controlled Oscillators" I read about how to switch in and out a capacitor or an inductor in a VCO, using a diode switch in order to alter the frequency of the oscillator.

Unfortunately this information is theoritical to me and I couldn't make my oscillator change its frequency.

Does any one have a practical example of a Switched reactance VCO ?

Thanks

You're right, Jim, my phrasing was poor. What I was trying to convey is that if you go to a store or catalog today and ask for "magnet wire", what you get will be enamaled/varnished/formvared wire - which is easily available. So if you are looking for cotton-coverd wire, don't ask for magnet wire.

And a note OT, I set up a new computer a few days ago. In the process, I managed to send out just TWO newsgroup messages with my real address in the header before I remembered to munge it. One of them was the message above. Damn, those spambots are good! My spam intake immediately jumped about 10X. My SWEN-related quota jumped from 2 a day to about 50 a day. No choice now but to simply wait for it die out.

But to those who say that the spambots are smart enough to detect and correct a simple NOPSAM in the address, I say "not so".

Do you have a scope and a pulse generator? If so, just make a simple
TDR (Time Domain Reflectometry) setup to measure the reflection from a
un-terminated or shorted far end of the cable. You will get much more
accurate results with substantially less effort.

Don't get me wrong, the MFJ-259 is a good instrument. It's just that TDR
is so quick and easy and unambiguous for propogation delay measurements.

Tim.

If you want to put a preamp near the antenna, you can run a DC
voltage up the coax by using RF chokes in the DC lines at both ends to
isolate the RF, and series coupling capacitors to block the DC. That is
how LNA/B/Cs are powered on most Sat TV receivers, and I have used it at
60 KHz, as well. You could use a Minicircuits chip that cost about
$1.00 by adding a couple caps, a coil and a resistor. Their ERA or MAR
series would do a good job, and the part is cheap enough that you can
afford to replace it when lightning takes out your preamp. I have some
rejected blank surface mount PC boards that will work for the part (They
were laid out wrong, and engineering had to eat the cost). You can also
do dead bug, or even use the old Vector Perfboard pins or standoffs and
build it point to point. They do need a ground plane, but are quite
stable.

These parts have a 50 ohm output, so they will match either 50 or 75
ohm coax with little problems. You might need a low pass filter to
remove out of band noise and signals to prevent overload, or if you want

to have real fun built a remote tuner at the preamp.

I worked on the Microdyne synthesizers using this method. It used strip line inductors, with a heavy ground buss along the edge of the board. The diodes were either forward or reverse biased to turn them on or off. you can't just let them float. Use a capacitor at least 100 times the highest value of the varicap to ground on the switching end of the diode, and as short as possible connections for the both ends of the diode. Connect a resistor to the diode and capacitor, and feed it a positive or negative voltage for forward or reverse bias. They have to be turned on hard, or they will rectify the RF and cause problems, but you can't exceed the current ratings, or you will damage the diode. we used + or - 12 volts for switching, and the diodes were used to switch the range at about 10% of the operating frequency. Its simple when you see it in front of you, but it is difficult to explain with text. This design was used in their 1200, 1400, 700, and 2800 series receivers, so you might find someone with a manual on one of these to see how they are built.

Hi Reg...

Well, the Google archive says it was from you. Perhaps you DO have
someone else posting under your name.

See below. Or is the "VF" column not actually velocity factor? OTOH,
I do agree with the posting below, that at low frequencies, beta
becomes dependent more on R than on L, and thus the VF changes.

Cheers,
Tom

Subject: Coax Cable vs Freqency

View this article only
Newsgroups: rec.radio.amateur.antenna
Date: 2003-08-12 17:41:24 PST

For anyone who may be interested.

Typical of RG-58 and RG-11 type cables.
Zo = Ro - jXo
Xo is always negative.
Angle of Zo in degrees. Always negative.

VF = relative velocity.

Freq	Ro	jXo	Angle	VF
50 Hz	967	-965	-44.95	0.034
1 kHz	220	-213	-44	0.151
10 kHz	80	-58	-36	0.41
100 kHz	56	-9.3	-9.5	0.59
1 MHz	52.4	-2.4	-2.7	0.63
10 MHz	50.7	-0.76	-0.86	0.65
100 MHz	50.2	-0.23	-0.27	0.66

Smith Chart calculations begin to be inaccurate around 2 MHz and
below. So
do SWR meters.

Even if you just ignore the fact that at low frequencies, R dominates over omega*L and affects the velocity factor, even if you just say VF=c/sqrt(LC), I believe there are changes with frequency. That's because with a good dielectric like polyethylene, C doesn't change much with frequency (AFAIK), but L decreases as the skin depth decreases. On large line, it's unlikely to be noticable, but on a line with an inner conductor radius only a few skin depths at the low end of HF, the change can be perceptable. Of course, the R term does dominate over omega*L at low frequencies. If the velocity factor were independent of frequency, I'd expect no dispersion.

BTW, I'd be a little surprised to find an inexpensive line which did not have polyethylene dielectric...polyethylene isn't expensive, and it's a good dielectric except for its low softening/melting temperature. You should be able to get a pretty good idea what it is from carefully measured VF, if it's a solid dielectric. There are very few inexpensive and low-loss plastics with as low a relative dielectric constant as polyethylene.

Cheers,
Tom

Tom,

It should be obvious when somebody asks how to find VF by using an HF
antenna analiser he is interested, like every other radio amateur, in the HF
value of VF.

If you agree with the table in the other posting, which gives VF vesus
frequency, and you are aware VF decreases with frequency, then how come you
didn't realise you had taken the value of 0.665 out of its HF context.

All my figures are correct.

> the oscillator.

I'm thinking the better, potentially workable solution is to just use a feedback loop (I'd say a Costas loop, but I'm not convinced this is the best option for AM -- just looking at the DC component of the Q output of the mixer gets you sin(phi), where phi is the phase difference between your LO and the incoming RF, which seems better as an error term than the Costas loop's error term, which is something like I*Q (before low-pass filtering) and gets you something like m(t)^2*sin(2*phi) and therefore has the potential to add different DC offsets due to the m(t)^2 term).

What I'm really planning to do is to build a quadrature receiver first and then see if I can build the feedback loop in software. If not, at least I'll be able to receive SSB and regular AM -- just not AM IQ binarual stereo, AM C-QUAM stereo, etc.

So, Reg, I note that (1) YOUR table shows more variation in VF over
the HF ham bands (especially so if you allow it to be extended down to
the 1.8MHz ham band, which I assume the MFJ analyzer would cover) than
the three significant digits of 0.665 would allow (the table showing
only 0.65 at 10MHz, and I suppose you'd go for about 0.64 at 2MHz,
maybe even 3.5MHz), (2) your posting in this thread of 0.665 did NOT
qualify the VF as being HF only, and (3) my posting DID say something
that SHOULD have indicated to you and anyone else who read it that I
was thinking beyond the bounds of HF with respect to large VF
variation. I'd STILL say there are instances where one should not
assume 0.665 for solid polyethylene at HF. There are instances where
0.64 and 0.665 are different enough to want to get the right value.
You're welcome to get all bent out of shape over that if you wish.

Cheers,
Tom

(I missed the original post.) I think you could get it from either
New England Wire or Kerrigan-Lewis, if you were willing to order a
minimum quantity. The "cotton" will be Dacron or something though.

Otherwise I would look on antique radio websites or find some defunct
equipment to disassemble.

Even the car radio type coax would probably have too much capacitance for the length of run you'll need. Yes, you could put a preamp (actually an active impedance converter) near the antenna in order to drive standard 50-ohm coax cable. I classify it as an "impedance converter" because you probably don't need or want much gain, just the ability to match the coax impedance. On the broadcast band any gain will likely increase the noise level as much as the signals.

If you don't have too much noise pick up from the house electrical wiring, etc you can probably just run a single wire feed line down into the basement. Keep it as far away as possible from any conductive material like rain gutters, etc.

3189. Car battery trickle charger?

Newsgroup: rec.radio.amateur.homebrew

This is not ham radio related but I know you guys have the answer.

I need to store a car unattended for a winter in the midwest. And I want to put a tricke charge on the battery.

I'd rather not buy a fancy trickle charger because it would probably get stolen. On the other hand I have a vast array of wall wart transformers.

If I connected one of these transformers how many milliamps should it put out at 12V? Or rather what's the least current that would do the job?

It seems that lead acid batteries can dissipate too much current as heat. In other words I could probably feed it one amp continuously. But would 100 mA at 12V do the job? I'd hate to lose a 1-Amp wall wart.

Thanks for your help.

Source record: 31357

You really don't want to trickle-charge the battery with high current..
that will cause the electrolyte to boil out and will kill the battery for
good. You want to use one of your wall warts to power a voltage regulator
such as a LM117 or LM217, so that you can adjust it to exactly the float
level of a lead-acid battery, that is, 13.6 - 13.8 volts.
Look up the data sheet for one of those regulators and build it to output
the float voltage. The battery will only demand the current that it needs
to stay fully charged. The LM117/217 can pass up to 1 amp, but more likely
will be limited by the capability of your wall-wart. Again, this is OK,
since the battery, once fully charged, will need only a few milliamps.
I recommend the LM117 or LM217 because of the low temperature extremes that
it may encounter in the midwest winter. The LM317 is rated for operation
down to 0degC, or 32F. I'll bet your winter will get down significantly
below that, so be safe and use a component that's rated to handle the
temperature extreme.
If you still need help after getting the data sheet for the regulator, come
back here with your questions.
Cheers!!!!

In looking at some of the options I was pointed to on this matter, it seems perhaps the first thing I should do is run a simple wire down into the basement as best I can and see how that fares. At least now Im armed with some alternative ideas should that method prove too lossy/noisy.

thanks again to all who responded!

I would guess that 100 milliamperes would be more than sufficient to
overcome any self-discharge of the battery, as long as the vehicle
doesn't have any electronics onboard which are drawing current.

>It seems that lead acid batteries can dissipate too much current as
>heat. In other words I could probably feed it one amp continuously.

You really don't want to do that.

The reason is this: in order for a car battery to be drawing 1 amp of
charge current on a continuous basis, you're going to have to boost
the voltage up fairly high. You'd probably exceed the electrolysis
voltage, and much of the current would end up breaking down the water
in the electrolyte into oxygen and hydrogen. If your battery's design
and chemistry don't allow the gasses to be recombined into water fast
enough, you'd be at risk of "boiling" the battery dry.

>But would 100 mA at 12V do the job? I'd hate to lose a 1-Amp wall wart.

Lead-acid batteries are happiest if you feed them a well-regulated
charge/float voltage, with suitable current limiting. Using an
unregulated or weakly-regulated 12-volt wall-wart is probably not a
good idea - these wall warts tend to deliver a rather high voltage
(often 16-18 volts) under conditions of little or no load. Depending
on the specific wall-wart you choose, and the condition and type of
your battery, you might end up electrolyzing away the water faster
than the battery can recombine the hydrogen and oxygen. Losing a
wall-wart would be annoying; losing the battery would be worse ;-)

The best thing to do is get (or build) yourself some sort of
well-regulated trickle charger. 100-200 mA is probably more than

plenty for this application, as long as it's provided at a well-regulated voltage. Most battery companies seem to recommend between 13.6 and 13.8 volts for a "float charging" application - at this voltage, the battery will self-regulate the amount of current it takes and will not overcharge or electrolyze itself. One knowledgeable amateur I know, recommends sticking to a lower 13.5 volts to ensure safe float-charging under a wide range of charge conditions and temperatures.

About a year ago I put together a simple float charger to keep the 65-amp-hour glassmat battery in our city's RACES ham-shack properly charged. It's a simple design, based on the jellybean LM317 three-terminal regulator IC and on the schematics in National Semiconductor's data sheet for this IC. My version includes reverse polarity and short-circuit protection, a charge float voltage which is adjustable over a span of a volt or so, and built-in current limiting to protect the wall wart (a 200 mA 16-volt unit, if I recall correctly). It's not a bad one-afternoon project and the components are the sort of thing most homebrewers are likely to have in their junk-box.

Schematic is at http://www.radagast.org/~dplatt/hamradio/charger.pdf

In this application, it's likely that the LM317 will be dissipating
enough heat to keep itself well within its recommended thermal range,
I think. In fact, it's a good idea to heatsink it - it can end up
dissipating several watts of heat under certain conditions which could
easily be encountered in this application, and could become rather warm.

This gets to the question of whether DC receivers can be used to copy
DSB and SSB:
By Goodman, W1DX, explained the problem in the 1965 edition of
"Single Sideband for the Radio
Amateur" (page 11): "Unfortunately, if both sidebands are received at
the detector where the carrier is
introduced, the carrier has to have exactly the correct phase
relationship with the sidebands if distortion is
to be avoided. Since exact phase relationship precludes even the
slightest frequency error, such a system
is workable only with very complicated receiving techniques. However,
if only one sideband is present at
the detector, there is no need for an exact phase relationship and
there can be some frequency error
without destroying intelligibility. " Modern SSB transcievers send
only one of the sidebands to the
detector, so this distortion problem only occurs when receiving a DSB
signal on a receiver that sends both
sidebands to the detector.

If they have already been punished in some way by the courts, then the
answer to your query is (or should be) yes. If they have not been punished
in some way by the courts, then, de facto, they have not been found guilty
of any crime, and are to be presumed innocent.

3198. Re: Car battery trickle charger?

Bruce:

As others have indicated, you really want to use a regulated charging voltage to keep the battery up... The voltage is important, however, more important to getting the design right is knowing how much of a drain the automobile puts on the battery when "nothing" is going on... Many cars will drain a good battery in about a month, just from the residual drain that is the result of such things as clocks and memories in radios and such. Add anything else and you've got a good chance of needing significantly more charging current than you might at first think.

You mention that you are worried about using a fancy trickle charger because it may get stolen, which implies that the car is outside in the elements, and not in a protected or secured environment. I'd be willing to bet that if you have to worry about someone stealing a trickle charger, you should probably be concerned about just about everything else too, once someone notices the car isn't moving and has a power cord going to it....

In addition, being concerned about a 1-amp wall wart, which are nearly a dime a dozen, may be false economy, considering the value of the car and items built or installed in it. Why wouldn't the tires and wheels disappear, or the battery itself? Same for radio and/or other accessories... or even perhaps the car itself.

If you do go and build something to keep the battery up, bear in mind that you are probably going to need something with a voltage around 16 volts or so, given that most regulators require a couple of volts of headroom over the regulated voltage. This may take you into a range of supplies or wall warts that is higher than you may have on hand anyway.

Get the least expensive battery charger you find and put a one of
those cheap little mechanical timers on it. And set the time to
charge the battery for one hour each day. It will be like driving
your car one hour per day.

Interesting circuit.

I have to beg a fair amount of ignorance about battery behavior. I've got a couple of the smaller sealed lead-acid batteries - the one on the desk right now is 4Ah.

Judging from what (little) I know about these batteries, I presume it would be safe to use your circuit as-is - that the maximum 200mA charging current, while intended to protect the unregulated source, would also be low enough to not overheat the battery.

In 1965 I can imagine that a Costas loop, two mixers, etc. was considered 'very complicated.' It doesn't seem all that horribly fancy by today's standards, however. But of course it's not like I've actually _built_ such a thing yet! :-)

It's ironic that DSB, which came about due to the ease of detection with diode (envelope detectors) turns out to be somewhat challenging to recover with a more sophisticated synchronous detection scheme.

Experimental Methods in RF Design points out that direct conversion receivers have become highly popular in the past couple of decades... this seems somewhat surprising; I would have guessed people back in the, e.g., '60s, would have gone to great lengths to avoid image reject filters and long IF chains.

Well, heck, if somebody wants DCC that bad, an old RFC (R F Choke)
is one "source." That old favorite of many moons ago, a 2.5 mHy RFC
was once an all-purpose thing, usually with 4 "pies" of windings and
lots of turns of small diameter wire that had either CC or DCC
insulation.*

I just don't know WHY anyone has to restore some old thingy to the
exact appearance it was supposed to have. Electrons won't care.
If the appearance is very important, just get a bunch of the wire in a
loose wrapping between two fat dowels and spray-paint the wire with
white primer. Primer has the dull surface, doesn't look shiny and
"false." <shrug>

* A 2.5 mHy inductance and 1000 pFd capacitor resonate very close
to 100 KHz and some way back in prehistory of the late 1940s used
that resonant circuit to make a "calibrator" spritzing harmonics way
up to 29.7 MHz. I did that as a beginner in 1947...then learned more
and got a Bliley 100 KHz crystal for "accuracy." Crude, yes, but a
lot more accurate than those wide-band tuning dials with separate,
uncalibrated "bandspreading" second tuning. Pfui.

==========

You guys are getting unnecessarily complex me thinks.

Yes a voltage regulator would be nice but not really essential. And
this might get stolen too. Besides, if I was going to go to that effort
I'd just buy a float charger (about $25).

The car is in a garage in a good neighborhood but the owner of the
garage is on and extended vacation. The theives I'm worried about are
neighborhood children. Actually it's the homeowner's car, I'm just

doing them a favor, and saving myself from having to go there to start the car once a week. So I'd rather not spend money when I have a plethora of wall warts.

The car does have an alarm but I don't know how much current it pulls.

Case, I've got one wall wart which has a 17V open voltage. When I pull it down to 12.0 volts the current is 120 mA. Might this work?

I could increase the size of the transformer if needed. It's just that I haven't yet figured out what's needed.

Lead-acid batteries have a rated current at which they can be float charged without causing any damage. This is the number I need, but have not been able to find it.

Here's a related article:
http://www.4unique.com/battery/battery_tutorial.htm

Although their normal price is about $15, float battery chargers (wall wart, coiled cord, little black box with LED, two cords with large alligator clips on the ends) are often advertised in Harbor Freight catalogs for $7.99. I must have half a dozen of them now, keeping batteries here and there up to snuff. I've never measured them, but they seem to do a real good job, and they're hard to beat at that price!

I have no connection to Harbor Freight except as a satisfied customer,

Should be fine. According to the Power-Sonic Technical Handbook
(http://216.87.171.32/manuals/techman.pdf) charge currents should not
be allowed to exceed 0.20 * C amperes - which would be 800 mA for a
4Ah battery. I prefer to stick to 0.10 * C amperes if I can afford to
wait overnight for the battery to charge.

I mis-stated the actual current limit provided by the schematic I
posted... this schematic is a modified version of what I actually
built, and has a higher current limit which would allow it to
be used with a larger wall-wart. The current limit is set by the
value of R4 - the charger goes into current-limiting when the voltage
drop across this resistor reaches 0.7 volts and turns on Q1. The
1-ohm value in the schematic sets the limiting point at 700 mA (not a
bad value to use when charging a standard 7Ah gel cell). 3 ohms would
give you a bit more than 200 mA.

In actual use, when charging gel cells, you're likely to find that the
charging circuit only goes into current-limit if the battery is quite
deeply discharged. Once the battery charges up to a significant
fraction of its total capacity, its terminal voltage will rise up to
13.5 (or whatever float voltage you've tweaked the charger for) and
the current flow will decrease, bringing the charger out of limiting.
It will then charge at a slower (and steadily decreasing) rate until
fully replenished, and will then draw perhaps 0.01 * C amperes of
float/trickle charge current indefinitely.

In order to charge the battery more rapidly, you'd need to set the charge voltage up to 14.4 volts or so (the "fast charge" voltage region) and then set it back down again once the current flow had dropped below 0.01 * C. Commercial battery chargers often use this sort of dual-voltage charging scheme to allow for faster recharge.

Note that you should _not_ use this sort of "higher voltage for fast charging" technique when charging starved-electrolyte (glass mat) lead-acid batteries - they are rather intolerant of higher charge voltages and should not be charged at above 13.8 volts. However, using a higher charge voltage really isn't necessary with these batteries... they'll soak up charge amazingly fast at 13.6 - 13.8 volts.

Keeping the battery charged is not the only reason to start the car once
a week.

Suppose it means that a car battery won't last long if you keep it
steady at top charge level, instead of decharge it down towards 50%,
sense the voltage level and charge it up to 14.4V (for this cold
area), and switch off the charger until it is down to 50% again....

I was told that a car battery wouldn't last long anyway for this
application, so even when my car battery is 6-7 years old, it
wouldnt't last more than a year when trickle charged, while it is far
better economy to buy a leisure type battery

As I understand it, that's exactly the opposite sort of regime that a
car battery prefers.

Car batteries are designed to provide large amounts of current for
engine cranking, even when cold. One of the tradeoffs in this design,
unfortunately, is that they do not tolerate deep (or even heavy)
discharge at all well. Discharging a car battery down to 50% and then
recharging it, repeatedly, is likely to greatly shorten its life. The
plates will quite literally fall apart.

Batteries having a different internal construction can handle deep
discharge quite a bit better. The older sort of "marine
deep-cycle" battery (designed for electric trolling motors) were
quite good - but I'm told that modern "marine deep-cycle" batteries
are more like car batteries in their design and no longer have a big
advantage in terms of deep-discharge life.

The best ones for deep discharge, today, seem to be the
starved-electrolyte (glass mat), and spiral-cell types. These are
often used for telecom backup applications, large UPS systems,
wheelchair motor, and electric-tractor/golfcart applications.

Leading eventually to the suggestion that perhaps your MFJ analyzer
isn't worth the powder to blow it up...

But I submit that you can make VF measurements on your cable with it,
which may be limited by the accuracy with which you can measure the
length of line you are looking at and not by the fact that you're
using a relatively inexpensive instrument. Here's one way. If you
look at a shorted stub 90 electrical degrees long in parallel with a
50 ohm resistor, you'll have to move the frequency by some value to
resolve a difference. The amount you have to move the frequency
probably determines the resolution you can get in VF. But if you make
the line 270 degrees long, you'll have three times the sensitivity.
So a hundred foot length of line, measured near 10 meters frequency,
would be long enough to get very good resolution--it'd be on the order
of 1530 electrical degrees. I'd be surprised if you had trouble
seeing the difference between, say, 0.664 and 0.665 VF. But beware
that the VF _does_ change with frequency, even over HF. There are
times when _I_ care about that, even if some others don't.

Cheers,
Tom

In normal operation a car battery doesn't get discharged to 50% and then recharged. The starter draws a large amount of current for a very short time and then the alternator keeps the battery charged and supplys the current for the vehicle. It seems to me like this would be very close to keeping the battery on a trickle charge.

Forget using coax or a preamp with that antenna. With an 80'
wire antenna for AM and shortwave reception, there is nothing
to be gained by their use, and you can degrade what you already
have. Just add a static discharge unit, connect the wire to the
receiver, and enjoy your antenna.

If you want to make improvements, you can modify the antenna,
and/or make an antenna tuner for it or use a different antenna.
But as it stands today, it should give you plenty of signal
for the use you have in mind. Running the wire into the
basement is not a problem - just make sure you don't damage
it, and route it away from metal objects.

SNIP

Back considerably before the beginning of time, around 1940/1941, my uncle bought a fancy Sears Silvertone console with multiple bandspread shortwave bands and the lot. It came with instructions for using a substantial center-fed dipole antenna with twisted-pair two-wire feedline. Back in those days twisted-pair feedlines weren't much different from rubber insulated two-wire AC cords - ZIP cord hadn't appeared yet. The impedance probably wasn't far off from 75 ohms.

The important point was that the balanced feed system and antenna reduced pickup of noise by the feedline. The close-spaced two-wire feed also made it less affected by routing.

Your 80 feet is a small fraction of a wavelength anywhere in the AM broadcast band, so the antenna will be a high impedance no matter where you feed it. 300-ohm twinlead might be a start in today's world. Is shielded twinlead still available? The other choice for feeding a band dipole might be plastic ZIP cord. The insulation is not great, but a 1500 kHz, who cares? The spacing is close, giving less effect of close objects, but the impedance would thus be low.

Just some thoughts, perhaps useless if you can't center-feed the antenna.

And if you build a voltage regulator using the recommended
LM317 and one of the wall warts you already own, you'll spend
less than 5 dollars. If you don't have a suitable wall wart,
adding the cost of that will still leave you WAY under 25 bucks.

And "keep alive" current for the radio and microprocessors
and clock and ?? totals how much?

>
> Case, I've got one wall wart which has a 17V open voltage. When I pull
> it down to 12.0 volts the current is 120 mA. Might this work?

Yes - if the battery starts out fully charged, and if the
current drain on the battery is only a few mA, and if you
add an LM317, a resistor and a pot and a diode to make a
protected (by the diode) voltage regulator. See the datasheet
at http://www.national.com/ds/LM/LM117.pdf for a diagram
(minus the diode). Add a diode between the input and
output of the LM317, banded end toward the input.

No - not a current. You want a regulated voltage for float
charging.

> This is the number I need, but have
> not been able to find it.

Read the article you mentioned (below). It says:
"Next comes the Float Step. This is a regulated voltage
of not more than 13.4 volts and usually less than 1 amp
of current."

Mike Terrell had a very good suggestion on switching diodes' current. Lots of folks have found out that higher current levels are absolutely needed. [me for one...:-)]

I might suggest an alternative: The CMOS switch ICs such as Dan Tayloe uses in his excellent Mixer for DC receivers. That CMOS structure is designed for higher signal levels with relative isolation of internal driving circuit to the switch portion.

I haven't tried that yet but am planning on that for next year.

>a thing yet! :-)

Most of you guys are knocking yourself out on what is little more than
an "intellectual experiment." Get a receiver and do a practical
experiment. An old receiver with a "BFO" isn't "sophisticated" and
will receive DSB and SSB just dandy, very "workable" if the LO is
warmed up and stable and the fine-tuning ("bandspread") can zero-
beat where the carrier is (or was). Do the same thing with a newer
receiver that has a "product detector" (nothing more than a mixer,
the same as what a DC receiver front end has but at IF, not HF).
Very "workable" and done all over in everyday HF comm, both ham
and maritime radio. Been done for decades.

The only "distortion" comes from not being able to set the tuning
precisely without some AFC. With AM and a "product detector"
(or BFO on), there's the carrier beat, strong, and won't go away
unless there's a terrific lowpass audio filter in there. If using a more
modern, basically-SSB receiver, it probably has a "RIT" or Receiver
Incremental Tuning that allows making the carrier beat almost to
DC. That's a frequency distortion still and manual tweaking can't
get the low-frequency, absolutely non-phase (or rapidly changing
phase) all the way out.

Can one get separated sidebands on AM DSB with a DC receiver?
Absolutely! No problem with a manual tuning DC receiver that has
TWO audio networks out of the mixer. A stereo-like effect (amazing

to hear for the first time) with lower SB = left ear, upper SB = right ear is possible, even if the tuning doesn't hit right on carrier zero beat. The "phase distortion" manifests itself solely in the amount of rejection of the unwanted side of tuning...too great a phase from ideal results in poor unwanted side rejection...very close phase and the the rejection of unwanted side is best.

>> However,
>> if only one sideband is present at
>> the detector, there is no need for an exact phase relationship and
>> there can be some frequency error
>> without destroying intelligibility. " Modern SSB transcievers send
>> only one of the sidebands to the
>> detector, so this distortion problem only occurs when receiving a DSB
>> signal on a receiver that sends both
>> sidebands to the detector.

Pfui. The old receivers with BFOs could "work" SSB. Problem is, those old receivers were so finicky and unstable, had such wide final bandwidths that those faults predominated. I have a nice 1948 National NC-57 gathering dust as proof of that. :-)

>It's ironic that DSB, which came about due to the ease of detection with
>diode (envelope detectors) turns out to be somewhat challenging to recover
>with a more sophisticated synchronous detection scheme.

Nooo...AM "came about" with absurdly SIMPLE components first, not even using any vacuum tubes! Case in point: Reginald Fessenden's famous Christmas Eve, 1906, voice transmission from Brant Rock, MA. Used a rotary alternator LF generator with a special (probably carbon) microphone in series with the antenna lead. The few who heard it along the east coast used galena crystal (the first point-contact diode?) or "coherer" or "liquid barreter" detectors. Technologically primitive by today's standards.

The existance of two sidebands in AM wasn't known for sure until the first Johnny Carson (John R. Carson, AT&T) published his modulation equations to show the presence of identical-information sidebands. Few labs had the equivalent of spectrum analyzers and vacuum tubes were still rare in the 1915-1922 era. "Detectors" of that early time were still the simple "rectifying" types...a regenerative detector still does "rectifying" (averaging of amplified signal input) to recover the modulation audio.

Long-distance telephony was the birthplace of SSB. Frequency multiplexing was the only practical way to cram four telephone circuits on a single pair of wires running many miles way back when. Frequency multiplexing uses SSB techniques. When RF amplifiers using tubes got going, the first SSB was four-voice-channel long-lines "carrier" frequency multiplexed modulation with radio replacing the wire pairs. Those applications needed AFC for unattended operation.

If you want synchronous detection of AM DSB, then you concentrate on getting a carrier reinsertion oscillator locked to the received carrier. Primary object is to get that lock. Worry about "phase differences due to distortion" in intellectual experiments. Lock guarantees that the synchronous detection will hold. There won't be any noticeable recovered audio distortion EXCEPT from unusual selective fading propagation on very long-distance radio circuits; you can hear that over old receivers with "rectifying" detectors.

Can you get a synchronous detection of AM SSB? Difficult unless the transmitter at the other end has sloppy carrier suppression. The commercial HF SSB stuff uses "pilot carriers" and the like to provide an AFC lock...deliberate steady tones at unused sideband frequencies.

>Experimental Methods in RF Design points out that direct conversion
>receivers have become highly popular in the past couple of decades... this
>seems somewhat surprising; I would have guessed people back in the, e.g.,
>'60s, would have gone to great lengths to avoid image reject filters and
>long IF chains.

DC receivers (also called "Zero-IF") came into popularity in Europe THREE decades ago. RSGB's Radio Communication magazines of 1973 were showing stuff in Pat Hawker's monthly column. I got interested in the Mike Gingell polyphase R-C network by seeing it first in there. The UK ham who was experimenting with it was Peter Martinez, G3PLX. Hams of today will know him as the innovator of PSK31.

To get good sensitivity with DC receivers you need ultra-low-noise mixers and following audio stages. Since the input side selectivity is poor (compared to IF xtal filters), those mixers need a terrifically high intermodulation specification which precludes low-noise operation. The Tayloe Mixer handles both superbly, the "mixer" being a CMOS switch IC with very low conversion loss as a mixer (all other passive mixers have at least 6 db loss). The CMOS switch IC has very low internal noise. Absolutely the best of both worlds.

In order to achieve selectivity and unwanted frequency side rejection the Tayloe Mixer system needs a basic LO at four times the carrier frequency to get wideband phase quadrature using digital devices. The In-phase and quadrature mixer output is in the audio range.

It seems to me that a modification of the Tayloe circuit would suit a synchronous detector application. How to go about it is another matter. Planning for THAT can start with an "intellectual experiment" but trying to implement it requires bench experimentation. There won't be any "distortion due to phase" once carrier lock has been achieved. Carrier lock methods have to concentrate on the narrow frequency region (tolerance of tuning offset) of the carrier. In practical reception the carrier of AM DSB is relatively constant (within a 20 db spread of amplitude if some AGC exists elsewhere).

Once the carrier is locked, the remainder of the detection process (recovering modulation audio) is straightforward. Any "phase distortion" is due to phasing network errors...which can be checked and trimmed independently prior to applying them.

Go for it! :-)

Stupid question but is there any possible way to get to the vehicle at least once a month or can someone you know and trust gain access to the car at least once or twice a month??? Unless you have a problem with your battery and/or charging system, having someone start the vehicle and let it run for roughly 10-15 minutes seems like an easier solution.

The nice thing about DC IQ receivers (apart from their zero image problem) is
that, any kind of demodulation can be solved in software, and is fully updatable
... whereas if it's done in hardware, you'd need new hardware for each mode
required etc.

The lack of image problems, simplicity of hardware and fully updatable
modulation schemes is what makes DC IQ so nice -. so it's not surprising to me
at all why it's becoming so popular.

It's closer to 100 ohms, but the KEY phrase here is twisted.
Zip cord and or twin lead isn't twisted (unless you twist it)
and it's the twist that imparts the self sheilding.

The twist improves the ability to reject noise and signals picked up by the balanced feed line but even untwisted, parallel lines do quite well. It is the fact that any signals are picked up by both lines equally and then cancel at the receiver input because they are in phase.

I looked through my collection of Microdyne manuals, and I don't have any with the circuit in them, so I have to work from memory. The best I can remember, they were switched by a ï¿½ 12 supply, and the series resistor was connected directly to the switching diode, where they soldered together on top of the capacitor. The other end of the resistor was connected to a simple transistor switch that converted TTL to + or minus 12 volt levels to switch the diode. I don't remember any coils, but the resistor and the switching circuit isolated the RF from the DC.

Another source of phase noise turned out to be the vias between the heavy ground buss on the top of the board, to the full ground plane on the bottom. Filling them with solder, and flowing the fop and bottom around the holes with 2% silver solder took the noise down quite a bit. The board was a combination of surface mount and through hole.

I had just fixed a number of design problems due to some parts becoming obsolete when they started to phase in a surface mount design. I was moved to a new product line, (RCB-2000 DSP based dual receiver and combiner system) before I could see how well the new boards worked. The only thing I do remember was the older board layout had a poor solder mask, and there were problems with solder bridges, and required you to disconnect all the wires and remove the board fairly often, but the surface mount had all solder joints on the top of the board so you only removed it to be cleaned, after the unit had passed all tests.

And low impedance lines are very close spaced so that the twisting is less
of an advantage.

3242. Tayloe Mixer Resistance Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-05 14:08:54 UTC
From: skavanagh73@yahoo.ca
Message-ID: <347cf68.0311050608.7301651a@posting.google.com>
Source record: 31209

There seems to be some difference of opinion on how to properly terminate Tayoe detectors (and other similar circuits) at audio frequencies. See the following published examples:

(1)G0BBL et al (QRP2001): load resistors are 220 ohms
(2)Hans Summers: load resistors are 1k
(3)9A2HL (on Hans Summers' website): Approx. 0 ohms, detector goes directly to op-amp pins
(4)AC5OG (recent QEX series, Part 1): Approx. 0 ohms, detector goes directly to op-amp pins
(5)AC5OG (recent QEX series, Part 4): 60 megohms (doubly balanced circuit).

In addition references 1-3 use a series 47 ohm resistor at the input of the detector, which seems unnecssary to me - the 50 ohm antenna should perform the function of the filter resistor, shouldn't it ?

I did some Spice modelling and found that my detector was well matched to the 50 ohm RF source for audio load resistances of a few hundred ohms (470 ohms worked well), and the conversion loss was a bit more than 3 dB when matched. With somewhat lower resistances the match was not as good but the conversion loss was reduced - 220 ohms may be close to optimum for both reasonable input match to 50 ohms and conversion loss. With higher (and much lower) resistances both conversion loss and input match degraded. The integrator capacitors were 0.1uF in this model.

Note that I am defining conversion loss as the relationship between the total power delivered to the 4 load resistances and the forward power at the input. With high load resistances the voltage at each load is indeed closer to the input voltage than for lower load resistances, but most of the power incident at the mixer is reflected back to the antenna. Therefore the conversion loss (defined in terms of power, which is what matters for noise figure) goes up.

I would be interested in the comments of those of you with some experience with these detectors. Also, can I assume (for the purpose of computing noise figure of the audio preamps) that the source impedance seen by the audio amps is simply equal to the load resistance that gives the best match at the mixer input ?

Follow the directions below and in two weeks you'll have up to
$20000.00 in your PayPal account. There is a very high rate of
participation in the program because of its low investment and high
rate of return. Just $5.00 to one person!

THAT'S ALL !!!

If you are a skeptic and don't think the program will work, I urge
you to give it a try anyway! It REALLY WORKS! Why do you
think so many people are promoting it ?

LOOK AT IT THIS WAY: If the Program is a total failure for you and you
never get even $1.00 in return, your total loss will
be the $5.00! If you are not yet a paypal member, there is no risk at
all!!! If the Program is only moderately successful for
you, your PayPal account will have several hundred dollars deposited
into it within the next few days! If you actively
participate in the Program, you could have up to $20,000.00 in your
PayPal account within two weeks!

Now let me tell you the simple details.

Getting Started!!

If you're not already a user of PayPal, the very first thing you need
to do is go to PayPal and sign up. It takes two minutes
and Pay Pal will deposit $5.00 in your account just for becoming a
member. That makes this program's total cost $0!!! Follow
this link to open your PayPal account:

https://www.paypal.com

Now log into your PayPal account, and send the PayPal account of the
person listed in Position 1 $5.00 PayPal will ask you to
select type. (Select "service" and put "$5.00 donation" for
subject.) When person in Position 1 receives notification of your
payment, you can simply copy this page and change the names in
position #1 & #2 & #3 as instructed. Remember, only the person
in Position 1 on the list gets your $5.00 donation. Send them a
donation then remove #1 PayPal account from the list. Move the
other two accounts up & add your Paypal account to #3 position. After
you have retyped the names in the new order,

IMMEDIATELY send the revised message to as many people as possible.
PROMOTE! PROMOTE! The more you promote the Program, the
more you will receive in donations!! That's all there is to it.
You are reading this message in usenet, and usenet is the best way
to spread the word about the program. Post this message to AT LEAST
200 groups in usenet(there are over 20, 000), after you send the 5
dollars to the person at #1. This will guarentee you a profit from
this program. The more groups you post it to, the more money you will
make!!!

When your name reaches Position 1 (usually in less than a week) it
will be your turn to receive the cash. $5.00 will be sent
to your PayPal account by people just like you who are willing to send
$5.00 dontation and receive up to $20,000 in less than
two weeks. Because there are only (3) names on the list you can
anticipate 80% of your cash within two weeks.

Anytime you find yourself short on cash just take out your $5.00
donation program and send it to 50 prospects. Imagine if you
sent it to 100 or even more. Most people spend more than $5 on the
lottery every week with no real hope of ever winning.

IMPORTANT!!! IN ORDER FOR THIS PROGRAM TO WORK, YOU MUST BE HONEST. DO
NOT ADD YOUR EMAIL IMMEDIATELY TO THE #1 POSITION, AND MAKE SURE TO
SEND YOUR 5 DOLLARS TO THE PERSON AT #1. IF EVERYONE WHO TRIED THIS
DIDN"T SEND THE MONEY, THEN NOBODY WOULD MAKE A DIME. 5 DOLLARS IS A
VERY SMALL INVESTMENT, ESPECIALLY WHEN YOUR ABOUT TO MAKE MANY MANY
MANY
TIMES THAT AMOUNT. IF WE ARE ALL HONEST, THEN WE ALL MAKE LOTS OF
MONEY!!

REMEMBER, you add your email to the #3 spot, and then move everyone
else
up 1(deleting the person who was formally in the #1 spot, and who you
should have sent your money to). DO NOT add your email to #1 when you
start this program. If everyone did this, then NO ONE would make a
cent.

THIS PROGRAM WORKS - JUST TRY IT

POSITION # 1 PAYPAL Account: lamsmo@aol.com

POSITION # 2 PAYPAL ACCOUNT: pepsiholic44@aol.com

POSITION # 3 PAYPAL ACCOUNT: bunnylovemedo@yahoo.com

Integrity and honesty make this plan work.
Participants who actively promote this program will average between
$8000
and
$12000 and receive the donations within two weeks.

This is not a chain letter. You are simply making a donation of $5.00
to another person. The Program does not violate title

18 section 1302 of the Postal and lottery code.

Remember -TIME is of the essence. YOU can choose to live Paycheck-to-Paycheck or live FREE from FINANCIAL BONDAGE. Become a part of the donation program and help people help people.

This program is about helping each other!

Success is a journey - Not a destination!

Start Your Journey TODAY!!!!

Hi all,
I have two HP power sensors: a HP 8481A and a HP8485A. After extensive calibration etc I learned that they differ about 0.4 dB at 12 GHz. No real difference (0.03 dB) on 500 MHz. Is that due to vswr alone or is one of the sensors maybe damaged? I use a HP 435B and a HP 438A. Please advise.
Regards,
Harke PA0HRK

> better economy to buy a leisure type battery
====
A leisure type (deep cycle) battery is fine for a moderate load for a
relatively long time ,since the plates are relatively thick.
However they are not suitable for engine starting purposes ,since brief
demands for a high starting current cannot be met reliably over time.
That's why car batteries have relatively thin plates with a large area
capable of supplying the high starting current.

If a car is kept outdoors it is worthwhile employing a small solar panel
positioned near the south face of the car with its lead plugged into the
cigarette lighter socket. This will keep the battery in a healthy condition.
I have seen these solar panels advertised by the car accessories trade.

The "first" complete receivers for HF were done over 30 years ago.
Totally in hardware.
Equally capable of CW or SSB reception without switching anything.

>The lack of image problems, simplicity of hardware and fully updatable
>modulation schemes is what makes DC IQ so nice -. so it's not surprising to
>me at all why it's becoming so popular.

Demodulation for In-phase and Quadrature had a much wider
application than you would normally consider, and by the millions
without software of any kind: NTSC chrominance demodulation in
TV receivers. Did it at the HF level, too, 3.58 MHz. :-)

I'm not positive about it, but I believe the first "image-less" mixer
systems were for radar applications in the 1950s, specifically for
monopulse radar tracking. I first encountered monopulse around
1959.

I agree that most everything can be done in software...provided one
gets the proper A-to-D arrangement capable of operating at extremely
low noise levels. Such is NOT easy.

DC receivers in general have many good features. But, one has to
do a realistic comparison versus the superheterodyne structure.

1. To get good sensitivity one has to work with truly low-level
signals that cannot take advantage of narrow bandpass filtering
ahead of the demodulator. A DC mixer input is relatively
broadband and that increases the total noise power in the
circuit.

2. Relative broadbandedness of the input absolutely requires a high IP3 since adjacent, normally-unheard signals can be at a high relative level. Few DC receivers have any AGC to the input stages.

3. The "image-less" condition (receiving only high-side or low-side of LO frequency) is resolved in demodulated audio and that absolutely requires a broadband phase-shifting network. Even with high IP3 specs on the input mixer, strong input signals adjacent in frequency can get through and fail to be cancelled in the audio network...if the adjacent signals are outside of the phasing network's range.

4. If the phasing network is simulated in software, then the microprocessor or microcontroller must be adequately shielded to avoid transitent RFI from getting into the input. Physical proximity would be very close and the input has no narrowband filtering to help that. Software demodulation will depend heavily on the type of processor and a lot of specs that have no direct relationship to software.

The end result is really a compromise of fewer parts traded for a whole new set of potential problems. One kind is not "superior" to another kind, just different.

==========

In the past I've maintained car batteries for many months using a small
(2" x 8") solar panel made for this purpose.

How much current could this put out? I don't know but I'm sure it's not
much. Nowhere near one ampere. It contained a diode and no voltage
regulator. This is the same effect I want to achieve with a small wall
wart.

If it's safe to float charge the battery at .01 C indefinitely, say 700
mA for a 70 AH car battery, then anything under 700 mA is also safe. My
200 mA wall wart is safe.

The question then is what is the self discharge rate, less things like
an alarm and clock?

That's good to know. At present I'm going to quit performing these "intellectual experiments" and start building something, and while I'm after C-QUAM AM stereo (rather than upper/lower sideband stereo), it's good to know what else _could_ be received.

BTW, if anyone wants to see the block diagram of what I'm planning to do, see here: http://oregonstate.edu/~kolstadj/RadioProj.gif . Keep in mind it's designed primarily for simplicity, not for phoenomenally good noise performance, sensitivity, selectivity, etc.

(I'd be particularly interested in comments on how to implement the low pass filters -- it seems one would want phase preserving filters such as Bessels or a cascade of a Chebyshev followed by an all-pass phase restoration filter.)

> Nooo...AM "came about" with absurdly SIMPLE components first,
> not even using any vacuum tubes!

Wow... I realize now there's a large gap in my knowledge of the history of the progression of radio inbetween "spark gap transmitter" and "diode-based envelope detector!" I have read of coherers before in Lee's book, "Design of CMOS Radio-Frequency Integrated Circuits" where he claims that nobody ever really did figure out _how_ they worked -- interest wanted as better detectors were available before they were around long enough for someone to do so.

You have a phoenomenal memory, Len... I wish I could recall the details as well as you have!

> Long-distance telephony was the birthplace of SSB. Frequency

I'm planning to write a (software) quadrature detector, and once that works, start worrying about obtaining phase lock so that stereo can be decoded.

> Can you get a synchronous detection of AM SSB? Difficult unless
> the transmitter at the other end has sloppy carrier suppression.

Without a carrier of some pilot tone (as a reference) it seems as though it's difficult to even claim there could be such a thing as 'synchronous detection.'

I took a quick look at the Gingell networks and they seem quite novel -- even made their way into a Real Commerical Product (a Maxim IC). (Interestingly enough, Dr. Gabor Temes -- who spent a long time designing telephone network filters before going into academia, where he is now, all of about 500' away from me here -- says there is still some black magic involved in making them work. :-))

Thanks for all the advice Len... I'd be offering to take you to dinner by now if you were halfway local!

That's what I meant -- DC receivers don't need them, and therefore it's surprising DC receivers have only really been gaining steam here in the U.S. in the past decade or two.

Then again, there's no arguing with performance: The GE "super radio" is, I believe, a triple conversion receiver!

I'd suggest you take a look at Dan Tayloe's own article in
RF Design for 1 March 2003. You can get a printable copy at

http://www.rfdesign.com

If you search for "Tayloe." Unfortunately, the figures aren't
available for downloading (I have my own paper copy) but the
details on the bits and pieces are all there. Good article.

OK, I got the block diagram. If you are using even a rudimentary
R-C lowpass following the two mixers, you need the parts rather
well matched in order to preserve identical relative phases. It is
important to HOLD the relative phase error at audio to a very small
number in order to do the In-phase/Quadrature thing. DSP will
work with BOTH magnitude and phase regardless of the kind of
modulation going into the mixers. You CAN realize a lowpass
function in DSP but the TI chip inputs probably needs some sort
of hardware lowpass filtering...? A simple R-C lowpass can be
checked out independently just from equal parts values to assure
minimum relative phase error.

Here's a good hint on melding hardware with software using DSP:

"Scientist's and Engineer's Guide to Digital Signal Processing,"
by Stephen W. Smith, PhD, California Technical Publishing.

Despite the title, this is a good text on DSP from the beginner's
point of view on to the more advanced. What is special is that
ALL the chapters can be downloaded absolutely FREE! :-)
[or pay about $68 for the hardcover]

http://www.DSPguide.com

Well organized book and a good "teaching style" to the writing.

Once you have the hardware fairly well in shape, it's time to go
nuts with the programming. This book ought to help whatever it
is you are going to code.

Actually, that's irrelevant and a historical curiosity.

The galena crystal and "cat's whisker" formed a rudimentary point-
contact diode. I had one of those in 1946, a Philmore Crystal Set my
Dad got for me (el cheapo quality, but it worked after a fashion). A
half year later a new electronics store opened up in town and they
were selling surplus WW2 radar set silicon mixer diodes, type 1N21
and 1N23. Put one of those in the Philmore and really "souped up"
the audio. :-)

As far as I've seen, the old telephony "carrier" equipment used ordinary
4-diode ring mixers, usually copper-oxide stacked plate types, the
small ones the size of old multimeter AC rectifiers. That was pre-1930.

I'm not sure when the In-phase/Quadrature demod/mod sub-systems
were first used other than probably just before 1940...or maybe in the
WW2 years. I know the beginning applications were there in the late
1940s.

The polyphase network was the subject of Michael Gingell's PhD
thesis in the UK. Material on that was seen on the Internet. Mike
is a USA resident now (or was a couple years ago when he had a
website...has a US ham callsign, too). A Japanese ham got busy
on that polyphase network and came up with an optimum set of
component values. That was published in QEX. Hans Summers'
website has links to all those.

Gabor Temes is a familiar name to textbook thumbers. :-) There
isn't a lot of black magic associated with the Gingell network, but it is
a thorough #$%^!!!! to try and analyze with its busy interconnections.
I stole a few minutes of CPU time on the RCA corporate computer,
using their LECAP (a frequency-domain version of IBM's ECAP...the
SPICE thing hadn't been developed yet) back in the 1970s. It worked
as advertised with only 0 and 180 degree audio input, producing nice
relative quadrature phases on all four outputs. Was surprised!

Some scrounged parts, not well measured as to values, and a quick
open-air toss-together showed excellent broadband relative quadrature
with less than 1 degree error in the 'voice' bandspace. Checked that
with a time-interval function on a homebuilt frequency counter.

>Thanks for all the advice Len... I'd be offering to take you to dinner by
>now if you were halfway local!

Thank you but I'll just wave as my wife and I roll through Oregon
along I-5 about once a year from southern California to Puget Sound
area of Washington. :-) Want to bypass the usual clogging just
before crossing the river into WA and vice-versa.

Hiya and sorry to be a bit late to respond. I offer a keyer that will work great for your application; in fact, there is at least one 10M beacon that I know of using it (WJ5O). Two messages, message chaining, beacon mode with delay from 0 to 99 seconds, nonvolatile memory, all the good stuff. http://www.hamgadgets.com.

An anti-alias filter at the very least! The TI chip in question is actually a microcontroller rather than a DSP; I chose that based on desiring a low power design and only requiring one chip rather than two (although I'd grant you that there are some, e.g., SO-8 package serial interface ADCs out there that almost don't count as another chip...) and, uh, because I already have experience with it from other projects. It can sample up to ~200ksps, but I was shooting for a much lower rather (perhaps some 20-50 ksps) since there isn't much number crunching 'oomph' available. (I.e., no multipy-accumulate instruction. In fact, no hardware multiplier at all! :-) I'll build the mind-numbingly fast DSP monster receiver that can pull a signal 10dB beneath the noise floor and turn it into CD quality audio once I get the simple ones working.)

> Here's a good hint on melding hardware with software using DSP:
>

How very interesting -- I actually have a copy of that with from Analog Devices (under a slightly different name); I always figured it was some third party and not the application engineers at Analog Devices that wrote it. Now I just have to crack the thing open...

> Good luck on that.

It should be up and running within a month here.

> I've seen it claimed in text, but no details, that a quasi-lock could

I figured that's what they might have had in mind. Seems like a lot of effort to avoid sending a pilot tone (but then again, what else to use the aforementioned DSP for... oh, wait... fancy digital modulation schemes... ok...)

Also regarding microcontrollers vs. DSPs: TI has an application note where they use so-called wave filters (which I know next to nothing about other than the name and that they can be designed to only require additions/subtractions and not multiplications in their implementations and hence execute quickly) for detecting DTMF. I thought it was pretty clever...

Pretty simple if the board you are putting it on is well solder masked.

Run down to Staples and get a package of Tac 'n Stik. Pity, that package is 2 oz and you'll need about a milligram. The two buck package will last you about ten lifetimes.

OK, now take a really tiny little ball of the stuff - less than a millimeter in diameter - and stick it on the circuit board right where the part goes. Squish the part down onto the blue stuff. The blue stuff won't hold it all that well, so you need to be a little careful, but you do gotta squish it good.

With your magnifier and an x-acto knife or dentist's pick, gently nudge the part around until all the pins are lined up on their pads. This is the hardest part -- be patient.

Timidly solder one corner pin. Take your magnifying glass and recheck all the pins. Move the part back so it's lined up again.

Solder the opposite corner - this is the moment of truth. Take your magnifier, and again check all the pins. Check them very carefully now, there is no turning back.

Take your soldering iron and run a big blob of solder across each row of pins. Be sure to give plenty of time for the first row to cool before you do the second. If you have a part with a bazillion pins, you may want to do a section at a time to avoid overheating the part. For something like an AD9850 with only a couple dozen pins, this isn't necessary.

Now take your solder wick and suck all the solder out. You need good quality solder wick for this operation. The cheap stuff seems to need a ton of heat. Take your magnifier yet again and carefully inspect each pin. (Needs to be a GOOD magnifier). You should have no little hairs of solder between the pins, and a thin film of solder under each pin.

Solder paste is probably better, but it's breathtakingly expensive and has a very short shelf life. Plus, you gotta use a heat gun which will heat a large section of the board, potentially removing other stuff you already mounted.

This takes a lot longer to describe than to actually do.

3265. Really good receiver for 14MHz

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-06 09:23:46 UTC
From: jvereker@wp.pl
Message-ID: <25102a3d.0311060123.17c590b6@posting.google.com>
Source record: 31232

Hello,

I'd like to build a simple receiver for 20m band. Saying "simple" I don't mean a "starter project" - I've built my first direct conversion receiver for 3.5 MHz already. I'm looking for something more complicated than basic DC receiver with 2 transistors + LM386.

My goal is significantly better CW reception - I don't care about SSB. Is an op-amp filter before amplifier the only method to get good selectivity in DC receivers? Or maybe I should try a simple superhet?

The most important thing is to choose a good project. I know there are famous kits like ones from Ten-tec etc., but in my case the costs of delivery could reach 3/4 of the kit's retail price, so I'd rather go for a well-established circuit from Internet and build it from the scratch. Could you recommend me a project that was copied with success by many hams, designed with the idea of an easy alignment by beginners i.e. based on "tolerant" circuits without tendency to oscillations and other surprises ?

thanks in advance,

jvereker@wp.pl

One other thing worth mentioning -- well, two.

If you have some silver solder, this is the place to use it. Silver solder flows better than regular tin/lead, so it works nicer with surface mount stuff. It's virtually impossible to get out of plated thru holes, tho, so it's not so nice for leaded parts, unless you never make mistakes. The difference is not so great that it's a must have. It's a LITTLE better on SM stuff. It's a lot shinier, though, so it looks good, but I wouldn't go out buying some for mounting one part.

In spite of the little bitty parts, you want to be sure you have enough temperature on your iron. For soldering the corners, you can often heat a trace a few mm from the pin and touch the solder to the trace. If all is hot enough, it will nicely flow under the pin. If you have a steadier hand than I, and a microscopic tip on your iron, you can heat the pin directly, but I have neither luxury so I gotta get by. I get a little lighter on the temp for the big blobs on the side, as I am always afraid of toasting the part. However, they always amaze me with their tolerance for heat. Still, I give the part time to cool between operations - maybe just paranoia. Obviously, the quality of the board comes into play here - you don't want to lift the traces with the heat. It does seem like both the boards and the parts are more tolerant of a short time with a lot of heat than a longer time with less heat.

Oh yes, if you discover you need to remove a part, the heat gun is the only way to do that, short of buying some super expensive desoldering station.

I've just tried some sample ChipQuik alloy made for removing SM parts.
It's a low MP alloy (based on Wood's metal) that you melt and blob over
the leads with a soldering iron. It works quite well, so I've bought one
of the kits - about 15 GBP.

3272. soldering aluiminium boxes ????? how

HI THERE
Just a thought , I have often made my own alum boxes , for projects
that I have built myself , and have always wanted to solder
the edges shut , for a more pleasing look ,
or sometimes solder two pieces together.

,Never mind the old resin trick etc ..
I wanted to proper solder them , with an iron ..yer

I have used different irons , and temperatures
various fluxes , and methods
and nothing has ever been successful

I know all about oxidiodsation , so I thought
could I solder it in a vacuum ??? or oxygen free
environment ??

say I get myself a large plastic box , air-tight joints
and Perspex top , with an air-tight fitting door
and a pair of fitted gloves , and a one way air valve
connected to the hoover , to withdraw some of the air
out of the box ???? , maybe even light a candle in the box
to burn up the last bit of the oxygen ??

the box would be large-enough for me to have all the tools
I need , small scrapers , iron , solder , flux , and the box iam soldering ,
etc

any thoughts ????

I would be prepared to go to this much trouble
if the idea would work . iam sure I can get air tight joints
by using rubber gaskets and expandable foam and glue
between the joints etc ...

>>>> I don't really want to hear about the construction method
down-falls in your replies , more about the theory of
soldering aluminium in a vacuum situation or lack of oxygen environment
<<<<

sorry to be blunt , but as so often happens in news articles
the main question or topic is often lost by the 3 or 4th reply
then it goes of a tangent to the main question .

anyway hope some one may be able to help ,
or has had experience of actually doing what iam trying to do

cheers for now

>....[snip]....

I understand that battery electrolyte becomes stratified if the batteries
don't receive the shaking they would normally get through vehicle motion
OR by charging hard enough that the electrolyte "boils" enough to mix
itself up.

I do know that the batteries I've used to power all of my 'shack radios
for the last 25 years do NOT last any longer (as I thought they would)
in a quiet/protective environment than the same batteries I put in my
vehicles!

Try this...
Get some good motor oil and put a drop on the aluminum...
Then scrape the aluminum oxide off under the oil...
Next get a good iron with enough wattage to tin the area under the oil with solder..
Then tin another piece and you can solder the 2 together...
A beter way perhaps would be if someone has a name that I can't recall but there's a compnay that makes a good Al solder that doesn't need a special flux..
I've seen guys demonstrating it at hamfests and fairs..
They generally show soldering aluminum beverage cans, Al pistons, lawn chair parts, etc.
I bought some and their special stainless brush and used it successfully..
But that was a few years ago and I have no idea where I put the stuff..
I'll bet someone here has the url.

FYI..
If you were in cosmic space and cleaned the oxide off 2 pieces of aluminum they would stick without heat, solder or flux!

Good and bad news..
I found my capacitance meter and measured the button and it's about 1500 pf.
The bad news is in my posting I transposed red and green and the correct
color sequence is: black, brown, green, red, gold, gray..
Black desigantes military, and 1500 pf by the next 3 but I still need to
know what the gold and gray designate..
Tolerance, temp coeff, and voltage but which 2 are designated and how?. Any
tips appreciated. A spec on this cplr would be appreciated.
tnx

Hmmm, I would have sworn the manual covers this, or is that just on the B model?....

I'll have to try this, but how about just connecting a length of coax, open at the other end and looking for the min Z. The longer it is, the less effect of any "end effect".

TO get around end effect, go to the shorted stub method...but...
I don't understand the 50 ohm in parallel. I'd put some large R in parallel when trying the shorted-end method such that there will be a reading. If I recall, mine stops above 1500 ohms. So, I'd put, say, 1 K in parallel then find the two freqs where I see some specific value lower than the resistor alone, then take the geometric mean for the stub's resonant freq.

From: dt@dt.prohosting.com
Message-ID: <u3cd1uu1u.fsf@dt.prohosting.com>
Source record: 31244

The Tac-n-Stik posting has some good suggestions. Here are a couple of variations.

1. Rather than use tac-n-stik, I usually use this procedure to initially position the part:

a. melt solder onto a corner pad (without the part)
b. keep the iron on the pad while...
c. using tweezers to guide the part into place.

Don't worry about getting a good looking joint yet. You just need mechanical stability and can always touch up the soldering later. If you're unhappy with the position, all you have to do is remelt the solder on the corner pad and move the part with the tweezers. When you like the position, solder the opposite corner to secure it.

2. The drench-and-wick trick works well, and I do use it for parts with extremely fine pitch. However, if you have a strong magnifier or microscope and a good quality iron with a fine tip, it is possible to just solder each leg in the traditional way. In that case, I'll still use the wick when I (inevitably) goof and bridge two or more pins.

David

>
>
>

SSOPs aren't too hard. Assuming your soldering iron has a high-quality
tip, solder-wick and a good pair of tweezers are all you'll need.

TSSOPs are a bit trickier, but still not impossible.

Ditto to all of the above.

> You don't say! Have you ever measured their voltage? Or is it written
> on the case?

Mine vary between 13.5v to 13.6v. If you open the little plastic
box between the transformer and the battery terminals you will find
a little adjustment that will let you tweak the voltage.

I have two different styles, one with curly coiled leads and one
with straight leads. I think the straight lead is older and has
been obsoleted. Too bad, because they made a nice low-current
adjustable power supply. :) The curly lead ones don't. But they
both seem to do a fine job of keeping lead acid batts up to snuff.

I have a couple on my bench. One set to 13.6v and one to 14.1v. I
put a gel cell on the 14.1v to charge after use, then on to the
13.6v to maintain ready for next time.

I have one in the barn. I cut off the clamps and put on a pair of
anderson powerpole connectors. A matching connector on my lawn
tractor allows me to easily attach with no concern for polarity
mismatch whether it is me or anyone else. I got 5 seasons from the
last battery, which is pretty good for a lawn tractor that sits
pretty much unused october thru april.

==========

Now we're getting somewhere. Myron said 15VAC at 600 ma. C/100 is
about 700 mA. Any idea what's inside the little voltage adjustment box?

Hi Bruce,
you have been given heaps of technical suggestions, heres mine.

1.Pull the battery out of the vehicle and take it back to your place.
2.Every week or so, check specific gravity with a hyrometer (sp) and
if it needs charging, do so.

This solves the problem of someone stealing the car unless they are
really keen, is simple, easy, and lo tech.

According to the manual the Harbor Freight charger is 15.5V. That seems a little high for a float charge to me. 12-volt LA batteries are generally float charged at 13.8V. Did you guys measure the voltage with it connected to the battery or under "no load"?

I think that's the wallwart, not the voltage applied to the batt.

Either way measures the same. The little box is a basic voltage
regulator circuit.

The recommended float voltage differs a fair amount with temperature and with battery type (liquid, starved, or, now very rare, gelled electrolyte). I'd check the manufacturer's specifications for the specific cell. Most are on the web these days. If I were floating a battery outside or in any other environment with substantial temperature variation, I'd want to use a temperature compensated charger, with the charger close to the battery.

Hello there, I am looking for plans to build an iambic paddle with PCB material. I had found one on the net but then got a virus on my computer and lost it when I reformatted my drive.

It was not one of the tiny ones, and now that I need it, I can't find the website to save my life!

So, if you have a favorite website with this sort of info, I'd appreciate it if you'd send the URL along to me.

Thanks in advance for any possible help.

Alright, so I built a voltage regulator with parts that I have around, an LM7812 with a few diodes connected to a 500 mA 12VDC wall wart. I hope you guys are happy now.

However I still maintain that a properly sized wall wart could do the job with no voltage regulation.

What sort of open-circuit voltage are you getting out of it?

>However I still maintain that a properly sized wall wart could do the
>job with no voltage regulation.

Hey, it's your battery (or your neighbor's) - if you want to
experiement and see if you can figure out whether that sort of
charging regime will appreciably shorten the life of the battery, go
for it!

I just figure that doing the job right isn't really very much harder
than doing it "maybe right, or maybe we shorten the battery's life by
a year?".

[and I really do like the idea of those Harbor Freight float chargers...
$7.95 for a tweakable-voltage half-amp charger is so low I don't
see much sense in homebrewing my own any more! I'll have to pick up
a couple.]

Hmmm, temperature compensate at a certain distance from the battery.
Can you model this Roy?

Won't happen. Or at least no one that I know of, in 20+ years of hamateur activity, has ever managed to do it.

The only way I know of to seamlessly join pieces of aluminum, as you describe, is by welding them. To do so, my understanding is that you need special equipment and an inert gas environment.

I suppose you could try using Epoxy, but I don't know how good the result would look.

I have the URL bookmarked at home, and a printed version of that page as well. I actually built that key with my very limited drilling/sewing tools, and haven't really operated it. Can't send the link until Monday, sorry.

When I operate CW I use my first attempt to build a IAMBIC key that uses two mini-switches back to back. I does make a little clicking noise and operates up to 15WPM. You can see some pictures at http://www.qsl.net/ik1zyw/hardware/key/index.html .

Still, both designs are very simple and give an idea of what kind of controls you want from a IAMBIC key (distance, spring tension, return speed, ...). Good for operating a few contacts at low speed.

Indeed. The TIG welding process is ideal for this, particularly if a
professional finish is important. But the kit *is* expensive and
there's a bit of a skill to be picked up (not *that* difficult,
though).

I've never succeeded with soldering Ali, what I do is the use
aluminium filings loaded into epoxy resin as a glue/filler.
My method is to.
Degrease the aluminium with Carbon Tet. or similar.

Stick some tape over the joint to be 'closed' on the side you can't
easily file, leaving a gap / fillet for the epoxy to fill.

Mix the epoxy as per normal then introduce the fileings. I find
diecast ali fileings are best as they seem to be more granular and
file finer grit.

'wet' the joint with some unloaded epoxy and then fill the joint with
the loaded epoxy using a spatula.

After its set I file the joint to an acceptable profile.

I have used this method to fill unwanted holes in diecast boxes with
good results. I'm not sure about its screening ability but its a lot
better than an open hole, both for screening and presentation.

The best epoxy I have used is called "JB Weld" which is incredible for
sticking ali and it is easily worked. Acceptable results are possible
with "Araldite" but it does'nt appear to have the same 'stick'
ability.

I have adapted to the "toaster oven" method -- and now I am smt'ng all the time:
my technique is to use an instrument looking like a pick to place a very small dab of solder paste on each of the pads, then place the device using tweezers. it takes about 4 minutes in the toaster oven -- some film capacitors, electrolytics can only be soldered ONCE. my technique is to do all the resistors and ceramic caps first on one run, then do the electrolytics and IC's second, the discrete and non-SMT devices are then soldered in by hand.

the method was discussed in Nuts n Volts a few issues ago -- using stainless steel stencils -- I find that I can do it by hand.

There is an epoxy out there is made for joining aluminum(I forget the name, its like JB-Weld, but for aluminum). You can find it at the larger auto parts stores, and you should be able to find it on the internet. When you grind/file it down, it's hard to tell where the aluminum ends and the epoxy begins.

Hey, you came to the group asking for help. It has been dispensed by
several responders who, by all indications, know and understand the
technology of batteries and charging much better than you. I've said to
several others like you, and I'll extend the advice to you as well... "If
you can't live with the answer, don't ask the question".
The responses to your question have been pretty much "spot on" correct. If
you don't want to take the advice of those who offered you help, then please
leave and revel in your own obstinance.
If you had taken the time to use the web and done a bit of research into
batteries and proper charging techniques, you would have saved several

3310. Absorptive Shielding?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-08 02:52:55 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <9FYqb.11772$fg4.443729@news20.bellglobal.com>
Source record: 31277
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

I was wondering if there is a radio frequency absorptive or otherwise lossy material with which one might line a conductive shield or use instead of it. I have noticed when tinkering with my DX-394 receiver that when I add a conductive shield so that it is largely enclosed there is an increase in the coupling of spurious signals from one part of the radio to another, e.g., from the 455kHz IF stage into the LW internal antenna and other parts of the input circuitry. I suppose this is because the energy that would ordinarily escape through the plastic lid is now reflected back and is trapped inside, thus raising the intensity. This may amount to a degradation of 3 to 6 dB. I use galvanised steel for the shield because it is cheap, easily worked, highly conductive and ferro-magnetic so it is a good material for keeping out both electric and magnetic external fields. Likewise, it keeps the internal ones in when it would be preferable to dissipate them. Any advice on an absorptive or lossy material for use from LF to VHF?

Would a carbon spray (if there is such a thing) do the job?
How about the antistatic foam material semiconductors and other devices are packaged in?
How thick would it have to be?

In article <vpt1BpzCC5aR@cc.usu.edu>, lara.louder@usu.edu says...

> Does anyone have a good recipe for holiday brew with low carbs?

Wrong newsgroup. Take another look at the title.
rec.RADIO.AMATEUR.homebrew.

The topic of said group is the home-based (hence 'homebrew')
design, construction, and modification of electronic equipment involved
in amateur radio communications work. Outside of possible imbibing, it
has zilch to do with home brewing of alcoholic goodies.

Ham radio does, however, make for a fun and rewarding hobby.
http://www.arrl.org has more info on it than you can pop a cork at.

3314. The Islander ...a homemade 7 Watt FM Transmitter...

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-08 05:12:05 UTC
From: braincambre500@yahoo.com
Message-ID: <85a87c6c.0311072112.264d41ae@posting.google.com>
Source record: 31281

Hello all,

Every now and then, I post my FM transmitter on different electronic forums, just in case someone is looking for a demanding, yet promising, project to make in the VHF arena!

I will give you my website further down this letter, but first, when you get to my website, just scroll down until you see the words...

'The Islander' A 7 Watt FM Transmitter

...and also read what Sir Harold had to say about his maiden voyage with the Islander...he did a spendid job on it, not to mention also making the open half wave dipole antenna!

Do enjoy all the projects at the website, it will be as much fun to make, as it was in makings them ourselves...that is...Sir Pedro and I (Patrick).

The website is at... http://braincambre500.freeservers.com

I thank each and everyone for taking the time read this message.

...and let the project begin ! ! !

Sincerely,

Patrick Cambre

P.S. If you are also looking for a dynamic one transistor FM receiver, I have one that I have worked on for nearly one year...and now it works like a little shining jem. I call it...

The 'Radio Shack Special' Project

It is also at the homepage...just look for those words above, and you will be on your way to a very very detailed construction of the one transistor FM receiver. The sensitivity and selectivity is outstanding!

Thanks. I'll have to experiment with resistors vs inductors.
I guess I always assumed you *had* to use inductors to keep
the RF off the supply line.

Just keep the leads short, and use enough current to turn the diodes
on hard. Let us know how you are doing with your project. I dug through
all the scrap modules and boards, but I don't have any parts of their
standard synthesizer module. I repaired a couple two digit serial number
units for engineering, as well as one that started with "P" (prototype)
so I doubt they ever trashed any complete boards or modules.

As I wrote I have DC RX, but for 3.5 MHz. What I need is monoband for
14 MHz. My RX is very simple and I am not sure if its circuit,
especially the VFO will work well in the higher frequency.

There is only one problem that I can think about when using only resistors to isolate the diode control voltage is the thermal noise voltage generated by any resistor. Especially in VCO control voltage lines, the thermal noise voltage generated by the resistor will add up to the control voltage, changing the capacitance and hence generate phase noise in the oscillator.

However, a reverse biased switching diode at 12 V should have a quite low absolute capacitance and thus, any switching voltage noise would have a very minimal effect on the capacitance.

It is perhaps somewhat expensive ,especially for larger areas , but
conductive paint would do the trick.

If you need a thicker absorbtive layer you can use the conductive
sponge which is used to pack old style DIL ICs.

Kind regards, Eike

That should not normally be a problem. The basic formula for
RMS noise voltage is SQRT(4 k T Bw R) with k = 1.38 x 10^-23,
T is temperature in Kelvin, Bw is bandwidth of noise, R is Ohms
of the resistor.

Assuming a VCO control loop bandwidth of 5 KHz, temperature on
the warm side at 320 K, and a resistor value of 10 KOhms, the
RMS noise voltage would be about 0.94 microVolts.

If the VCO control voltage range is 4 VDC and the tuning range is
approximately linear over 4 MHz, that 0.94 uV will produce a phase
noise of 0.94 Hz RMS. Not a great deal...:-)

It's more than likely that stray voltage garbage in the circuit from
other sources (such as inadequately bypassed supply rails) would
be a potential problem. [pun intended]*

I doubt that such will work below VHF. Absorbing foam polymers
have been used for decades on antenna ranges for the microwave
region. Emerson & Cuming have been making various grades of
that for a long time. Search the Web for them and see what they
say and what they have for information.

I've seen a fair amount of electronic hardware over the last half
century and haven't encountered any equipment operating below
1 GHz that used any sort of "RF-absorbing" material.

The best bet is just plain old metal shielding, bypassing feed-thrus,
series inductances, etc.

I've seen ads in an EMI-related trade magazine for a ferrite (or ferrite-loaded polymer I suppose) material, in the form of an adhesive-backed sheet which can be cut and then stuck onto the tops of ICs (CPUs, DSPs) or placed between adjacent circuit boards, to help reduce unwanted emissions. I don't know whether this stuff's useful frequency range goes low enough for the OP's needs, but it might be worth a look.

Typically the DC end of the resistor is heavily bypassed to ground, thus the resistor is more or less in parallel with the resonant circuit reactances. In many cases a 10 kohm resistor would heavily load the Q of the resonant circuit and thus, a larger resistor (say 1 Mohm) might have to be used. This would increase the noise voltage ten times.

Looking first at a free running VCO with the control signal coming through a large resistor. The noise is generated at an infinite bandwidth, but the varactor (and other stray) capacitances (often in the order of 10 pF) in the resonant circuit will form a first order RC low pass filter with the -3 dB point at 100 kHz .. 1 MHz. Above this frequency the noise power drops by -3dB/octave, thus it contributes the same amount of noise power as below the crossover point.

Thus, for a free running VCO, the noise voltage could be up to 10 times larger than previously assumed at 5 kHz bandwidth. With a larger resistor, the boise voltage would be in an order of 100 uV RMS.

If the VCO is part of a PLL, the only effect is to the noise frequencies _inside_ the loop bandwidth. The noise outside the loop bandwidth is _not_ attenuated. The loop bandwidth can be quite narrow in the order of 100 Hz in some channellised systems especially if a fixed prescaler is used. The loop bandwidth could be well below 100 Hz in VHF/UHF FM gears if the audio (and CTCSS) modulation is injected directly into the PLL control voltage line. Thus, the PLL cleanup operation affects only a minuscule part of the noise bandwidth.

> If the VCO control voltage range is 4 VDC and the tuning range is
> approximately linear over 4 MHz, that 0.94 uV will produce a phase
> noise of 0.94 Hz RMS. Not a great deal...:-)

At least in many VHF/UHF systems, the VCO sensitivity could be 10 MHz/V and with a noise voltage of 100 uV, the phase noise would be 1 kHz. This would severely limit the SNR obtainable when using FM in addition to the increased reverse mixing. These kinds of problems are common with VHF/UHF FM gears.

However, some badly designed simple up converting general coverage HF receivers could suffer from quite high phase noise, if a single VCO is used without switching in reactances. In such receivers, any CW signal would sound as it is coming through the aurora :-).

Clearly, this discussion shows that picking the right initial assumptions, quite different conclusions can be made.

i have seen this site a number of times and spent some time reviewing
it in detail. his designs are pretty simple. and i would say, too
simple to be replicated and used.

for instance, he has a transceiver with 50mW output. while this might
be a good experiment, don't expect to work all the grids using this
one. similarly, his receivers (like the one SSB transceiver with three
transistors) might work across the lab bench. but it will hardly
suffice as the main rig in a station. in anycase, i think we are past
the point of measuring rig complexities with the number of active
devices. these days the active devices often cost less than some
passive components. I get decent RF low power transistors for less
about 3 cents each.

This week, i finished an 2M transceiver too (The schematics are still
being drawn out, i will post the circuit soon.) It uses (i just
counted) 19 transistors, two ICs and two diodes. The total cost of
material is still less than 10 dollars (at least in india). Quite
often, using active devices often reduces the cost rather than
increasing it. For instance, a phasing type of SSB transceiver cost
far less than a single collins mechanical filter. Yet, the performance
is as good if not better than a that of a filter type ssb generator
and all most all circuit complexity is at audio frequencies.

too often, we tend to look for the simplest (read least active device
count) system only to find that it doesn't work as advertised. It is
more likely that a slightly more complex circuit turns out to be more
stable and easier to get going that the least count winner.

easy replication of a design means that if you build it again, you
should expect the same performance. this usually means that you
extract a little less out of each stage than it is capable of leaving
some head-room for device variation and component value tolerance.
That is the reason why many of us here like to reuse certain blocks
(like broad-band feedback amplifiers) over and over again.

finally, i would say, that it is not enough (at least for me personally) to build something that makes a contact across the city. one should aspire for the best quality in terms of whatever your personal design goals are. Often, unrestricted by the need to include all the features (like multiband, PLL, etc.) and with the ability to use one off components, the amateur can spend more effort in building and aligning his rig that a commercial counterpart. That is a goal worth acheiving. it is not enough to match a commercial rig in terms of performance, it is just a moderate challenge to build something that that surpasses it by your own criterion.

Precision machining. The tolerances are tighter than most connectors.
Some of the newer RF connectors are even worse. They have to be machine
assembled and ordered made to length, or with a single connector.

From my few weeks in the microwave absorber business :)) , IIRC an absorber has to be ELECTRICALLY at least nearly a quarter-wave thick to be really good. The ferrite loading helps accomplish this. A good impedance match to the 377 ohm impedance of free space helps avoid reflections. For a broad band, this encourages the use of the deep pyramid absorbers to taper the impedance mismatch.

Some hams have found that absorbing material inside to covers of preamps in the __hundreds of MHz region___ reduces the likelihood of self oscillation. I've never seen a serious suggestion that absorbers would help in the few-MHz region.

Regrettably true. The SMA/SMB series are the last ones I know of that still have big enough individual pieces (barely) to be hand-assemble capable. Those tiny center pins are a real pain, though...

>assemble capable. Those tiny center pins are a real pain, though...

The basic SMA design came about almost 30 years ago as a small
coaxial connector that would work on up to X-band (8 to 12 GHz).
In order to even approach that frequency ALL the mating surface
tolerances have to be precise in order to avoid discontinuities that
raise the VSWR. Tighter tolerances mean greater cost to produce.

The old "UHF" connectors (SO-, PL- numbers) common on amateur
HF and low-VHF equipment were obsolete for new designs a half
century ago. Those are cheap because there isn't much QC on
them and the tolerances are sloppy in comparison.

SMAs used with semi-rigid coax are quite easy to make once you
get the hang of it and are incredibly durable physically and in all
kinds of environments. The solid center conductor of the semi-rigid
becomes the "pin" just as in the TV set F connector used with
RG-59 75 Ohm semi-flexible. F connectors are good to 1 GHz
(with some higher VSWR than others) so don't anyone knock the
method. SMAs are dandy to use with stripline in aluminum hog-
out enclosures.

SMBs are on the SMA basic plan but are push-on, pull-off mating
for quick connect/disconnect. Okay for limited testing in systems
and prototyping. Note that BNC males with the outer bayonet
connecting sleeve removed will mate with N females for quick
testing too (no remarks about miscegenation, please...).

You can spot a pro in microwave RF work by the extra 3/8" across the flats wrench within easy reach. An open-end, closed-end combo 3/8" wrench is only about 3 1/2" long (Craftsman). I used to carry mine on the business keychain in my pants pocket...:-)

3347. Re: Tayloe Mixer Resistance Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-09 18:37:39 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3FAE8973.7EEF0B25@cox.net>
Source record: 31163

Some quick notes on the application of the Tayloe mixer to answer some of your questions:

Recovered power is not relevant for this detector depending on the kind of post detector pre-amp is used. Detected power might be more a concern if you were driving something like a discrete bipolar transistor post detector amplifier.

Infinite input impedance (such as the + side of an op-amp) allows for best detected voltage and best adjacent frequency roll-off. Instrumentation amplifiers do this best, but are more noisy when run at reasonable gains. Remember, the detector acts as a bandpass filter. Best frequency roll off gives the best high signal performance.

You can also present feed the "-" side of an op-amp, and use the detector more like a current source. The detector bandwidth is more flat when this is done.

The best low noise compromise seems to be to feed one side into "-" and one side into "+" on the post detector amplifier. The balance is compromised a bit, and the detector roll off is not a sharp, but it does give best sensitivity without having to resort to an instrumentation amp with 1000x gain, which would kill the dynamic range of the front end. "Low noise" instrumentation amps are kind of noisy unless they are run high gain. A gain of 15x is the right kind of ball park for the voltage gain of the post detector preamp.

When a 50 ohm source is used, the 4:1 multiplexing action makes each output look like a 200 ohm impedance (neglecting switching times and switch resistance), so 220 ohms is close to the best power match.

Any resistance in series with the following preamplifier introduces noise, which is not a good thing when best sensitivity is the objective. Some series resistors in the inputs to an op-amp, can give better frequency roll off (high signal level performance) at a cost of some sensitivity (a trade off). Modeling can show you the roll off trade, calculations can give you the noise voltage (sensitivity) impact. 220 ohms is a high here (over double the noise voltage of a 50 ohm system). This resistance matters less if you are simply interested in ok sensitivity performance, which is a "don't care" on something like 40m and lower.

The 50 ohm on the input to the detector is not needed. The system impedance provides an equivalent input "R" for the detector caps to work against.

A low noise op-amp is desirable for the post detector amplifier. 50 ohm system noise is around 0.85 nV/squarerootHz. Some opamps have noise performance to match this such as the LT1115 (0.85 nV/squarerootHz), but are about $4 each and you will need two. I have heard that some folks have built their own low noise preamps using 2N3904s, but I have not really tried that.

More common decent op-amps are in the 4 nV/squarerootHz range, such as the LM833 or the NE5532, which are under $0.50 in a dual opamp package. Recognize that 0.85 nV/SqrtHz noise rating compared to a noise rating of 4 nV/SqrtHz is a 13.5 db (sensitivity!) difference.

Perfect receiver sensitivity (3 db S+N/N) is about -148 dbm with a 500 Hz bandwidth. In practice, I have gotten -142 dbm sensitivity performance using a pair of LT1115s and no RF preamp. With this rig on 20m, QRP cw signals in a contest could be heard weakly but clearly that were not there on a K2 (A/B comparison using the same antenna). With a NE5532, expected performance is in the -134 to -136 dbm range.

Beware when an op-amp claims low noise! The specification sheet will give the noise vs. frequency curve. Many "low noise" op-amps, are only low noise at 100 KHz. Be sure to check the noise curve at 300 to 1000 Hz!

Practically speaking (as one neanderthal to another...):

That method does work if there's no drill press available. But, be
sure to buy an extra drill bit for the size desired going around the
rim. Had to do that with a 4 1/4" diameter speaker hole in an 1/8"
aluminum rack panel (alloy tougher than 2024 but not as stiff as
6061). That included light oil lubrication. The "center" didn't
"drop right out" but centerpunching the many holes right allowed
using old wire cutters to snip the narrow left-overs between holes.

A Hand File to complete?!?!? Good grief, no. A Dremel Moto-Tool
with several "mill type" cutter bits is much preferred to smooth out
the rough edges. Note: Home Depot, Lowe's, Do-It-Centers, OSH,
all carry extra bits for Dremel Moto-Tools, many which aren't
included in the Dremel kits. Use a biggie mill cutter to hog out the
worst, go to a small bit to smooth those edges. One of several
grind wheels can be used to finish it off. Takes a steady hand
(usually both hands if panel is in a vise).

Absolutely needed: A scribe marked circle on the panel as a guide!
Maybe two concentric circles, the inner one slightly smaller than
desired as a "target." If one gets sloppy, it's possible to cut farther
out than the inner, smaller "target" circle. To get the scribed circle,
use a grade-school compass in REVERSE, the "pencil" part in a
small drill hole at center, the "center" part (pointy end) doing the
scribing.

Dremel also makes a dandy mini-drill-press stand for the Moto-Tool which is just lovely for through-hole PCB drilling. I use one for that plus the AC line voltage adjusted with a Powerstat (Superior Electric) variable autotransformer to control the "drill press" speed. BTW, liquid hand soap, slightly diluted, works out as a PCB drilling lubricant and washes out with hot water...and can be used with a rough-surface sponge to buff out surface oxidation on the copper foil or removing tiny burrs in the drill holes.

That would be the "ECL in ps" [ps = picoseconds] series of devices, have 10E
or 100E prefixes. Very high speed -- max clock rates typically 700 MHz to 1
GHz. [Stretching it a little to refer to them as picoseconds, IMHO]

Thanks to everyone who has responded. I think the conclusion is that at the frequencies I'm interested in, and the available space inside the radio (a little RS DX-394 table radio), it's impractical to absorb the 455 kHz crosstalk energy from 2nd IF to frontend. Better to attempt to compartmentalize the radio. That may prove to be impractical also as it would appear very difficult to make small (removable) shields over the IF section that would not have gaps. However, I'll examine the pcb layout more closely to see if there are any viable paths for the sides of the shield box.

Source record: 31168

One additional item to model is using highly reactive antennas.

The Lowpass rolloff point caused by the integrating capacitors is controlled by the effective antenna impedance.

While one can assume 50 ohms, more or less, for a matched antenna, using the Tayloe detector in a general coverage system should be calculated to assume the antenna has massive mismatches at most frequencies.

I did some simplistic modelling and the results were interesting. To control the detector rolloff, I'd be tempted to use a low gain RF preamp and perhaps a small attenuator pad feeding the mixer....

Besides, as I recall, the Tayloe detector responds to harmonics of the LO and so some frequency selective flters in the RF preamp might be useful.

All in all, The Tayloe detector has some benefits, but as with most detectors, adding some components can enhance the system performance.

>
You are right of course.
My fault. I didn't read the OP's question thoroughly enough. I was
thinking of freq. above UHF. Absorbing material for lower freq. has
to be a LOT thicker than 1 cm. This can easyly be seen in any test
chamber.
With wavelengths longer than the compartment of the circuit I do
not see the necessity of absorbing material. Common construction
practice as pointed out will be suficient. Or just bury the device
6 feet deep in the soil ;-))

Kind regards, Eike

Small gaps won't matter as long as they are shorted out at one or both ends.
A well-fitting cover would do that. You'll observe that commercial gear uses
very thin tinned steel? for shield boxes. The lid edges are bent into spring
fingers to hold them in place.

It is good for many purposes, even up to 432MHz - in spite of what
somebody says. In the local radio club the problem is that they don't
like to solder and even SO239/PL259 means a great problem. Not to
mention a club which went into a very large scale of antenna
installations for CQ-WW contest last year and discovered that some of
the antennas which were put up few days before didn't work any more

With all the available semi-rigid cables with connectors available as
surplus it has never been neccessary to mount such connectors, got a
few hundred cable connector 10 years ago, but really not needed them,
and I do have 10GHz SSB transverter with SMA connectors

Cheap garbage is out there, but after you've seen it, you will never
use it again. I have seen imported "N" "ell" adapters with over 20 dB of
attenuation. I have seen crappy SMA connectors that pop apart before you
can even tighten them to the chassis connector.

I will not buy or use garbage. I have some Omni-Spectra, and a pile
of surplus SMA connectors left, plus a pile of modules from commercial
Sat receivers, and telemetry equipment that should last me a couple
years.

> have this information?

Your best bet is to dig around at a hamfest (ham radio swap meet)
for an Expo manual. Motorola hasn't made those radios for at least 12
years, and no longer has any support or manuals available.

You may want to ask this same question on
http://batboard.batlabs.com.

For locations of ham radio swaps near you, it's best to locate a
ham radio club. Check the listings at http://www.arrl.org

Good hunting.

==========
There are High quality PL259 connectors with teflon insulation where only
the (gold plated) centre pin has to be soldered .
The braid connection is like an N-connector with a 'flanged braid insert'
.
They are relatively expensive (GBP 3.00 = US$ 4.50) ,yet I have adopted them
as standard for all the necessary 'UHF' connections in the shack.
In the UK these connectors are available from Westlake.

Tektronix is trying to manipulate the oscilloscope market. Today I learned from my local dealership that they are required by contract to destroy every scope which is traded in for a new Tektronix scope, regardless of age or condition. So if you decide to trade in that old scope for a Tektronix, know ahead of time that it is NOT going to end up in the hands of a ham, or of some kid learning and experimenting in electronics on a tight budget like I was thir... er, twenty years ago. No, Tektronix needs to raise their profits by destroying every used scope they can get their greedy little hands on, regardless of who feels the pinch!

Interesting, last I heard (and that was only a few weeks ago) the Tek
Country Store was still in business, selling their used trade-ins, among
other things. Could your dealer be blowing smoke up your behind?

> Does anyone have a good recipe for holiday brew with low carbs?

Lara, please forgive some of the other respondents - they're not well rounded in the art of "homebrewing." After all, this is amateur radio homebrewing.

OK, on to the ale.

Get malt with a high conversion ratio - that is, you want malt that will ferment to dryness without much residiual sugar left behind. Left behind sugars can also mean flavor, so your brew will lack a big, malty flavor, but that's OK for a holiday brew style.

Are you using all-grain or extract? Munton & Fison extract usually does well in this area. If you are using all-grain watch your mash temp and get the best extraction that you can. Leave out all or most of the specialty grains, and keep the SG reasonable. You can even sub some cane sugar for some malt to reduce the unfermentables. Remember, though, lots of alcohol is lots of carbs.

Next, what do you plan to add to make it "holiday?" Most folks like orange zest and strange spices. I'll leave that up to you as even my Belgians are sans the strange stuff.

Next is the yeast. Get a Belgian yeast with high attenuation, that is it will ferment out all the malt sugars (or at least most of them). I like White LAbs yeast in vials - no need to "smack" or any of that nonsense.

http://www.whitelabs.com/craft_belgianyeast.html

To recap, get good extraction so that unfermentable sugars are low, keep the SG reasonable (most Belgian beers are not so reasonable), and get a high attenuation yeast to ferment the brew to dryness.

Finally, start real soon or it won't ready.

I think I'll go pop the top on a kwak-clone that I made last spring.

Frank - this is how big business works. They're not in business to do
favors for you, they're in business to make money. Period.

Teletype Corp. used to do the same thing with used Teletype machines.
Motorola used to do the same with traded-in 2-way radios (I had a friend
who drove the truck to the crusher.)

That's the way it works, Frank....

<snip>

Do you have hard evidence of this, such as an official statement
from someone at Tektronix in authority to make such statements?

I think your local dealership is pulling your leg. I visited the
Tektronix company surplus store less than four months ago, and found a
generous assortment of older 7000 and 11000 series mainframes and plug-
ins, many of which were in perfectly usable condition.

Don't even get me started on the seemingly vast quantity of Tek
scopes and other such goodies that seem to be in constant availability
on the surplus side of things (hamfests, stores like Kaiser Technologies
in the Bay Area, etc.)

If this really is true, its a shame. I've been using and repairing old
Tek scopes for about 30 years (!), and love to see kids, hobbyist,
and hams get their hands on them.

Realistically, 'scopes Tek gets in
on trade will be a very small percentage of the number out there, so
it should have little effect.

Steve

Yes, this is how business works, but that doesn't mean it works well, as many companies rely on their longstanding reputations as 'good guys'. The info I received came from the GM of Radar, Inc. in Spokane. Whether the policy was initiated by Radar or by Tektronix, or applies to any other brand, he didn't say. What he -did- say was that he has had to send several dozen scopes the the incinerator since this policy began not long ago -- and some nice ones, too.

Either way, it still sucks.

Has to have been Radar's policy (and a stupid one it is, too). I
don't see Tek doing it because Where do you think they get so much of
their inventory for the company surplus store?

A lot of the items at the Country Store are prototypes, special modified
units used as test fixtures, etc. that wouldn't have much appeal to
end-user customers as much as to experimenters.

3386. Michigan Mighty Mite question...

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-11 04:29:46 UTC
From: jim&julz <shrumj@spamsucks.madisontelco.com>
Message-ID: <bopo95$bkg3$1@news3.infoave.net>
Source record: 31102

Greetings...
Has anyone here actually built the MMM and had success w/ it? I've tried it 2 times on the bread board and each time ... nothing. I have followed the schematic perfectly, but I get absolutely no output at all (per the frequency counter, and FS meter).

The only thing that I can think of that might be off, is the crystals that I'm using. They're not specifically transmitter crystals... just ones that I've scrapped out of junk. I was using a 10.145Mhz Xtal w/ the 30meter coil directions. Is there actually a difference w/ xtals, other than frequency? Also for the variable cap, I'm using a variable cap from an old am/fm radio... I assume this will work.

I was just wondering if anyone has tried and failed, or tried and succeeded. Any help would be much appreciated. Thanks

Jim

If the policy exists, it is stupid. A used Tek scope may present some
compitition to a new Tek scope, but it presents much more compitition to
the new scopes of the lower price manufacturers.

You have to be a corporate "bean counter" on a rant to come up with
schemes like this. You're right, Frank, a $500 used model isn't hardly
competition to their latest-greatest $20,000 model. Mr. Bean-Counter
would like to think they could eliminate such competition but odds are
Mr. Bean-Counter wouldn't know a o'scope if it bit him in the arse.
If Tek is really doing this nowadays the only purpose it serves is to
make them appear as knuckleheads.

One rather large electronic mfr that I used to deal with had an "outlet
store" where they sold the trade-ins, factory refurbs, etc. Basically a
scratch-and-dent outlet. Prices were only maybe 25% less than the good
stuff...the biggest advantage was not having to step thru the corporate
ordering nightmare spending days, if not weeks, playing phone tag with
some "account representative" who was the only person authorized to take
your order.

The outlet store made too much sense so they closed it.

Tektronix is a good and reputable company. Don't care what anyone might think, I know better. My uncle (Warren K. Dallas) helped establish the groundwork for a reputation since 1947, that prevails within Tektronix to this day. Any doubts, read the book "Winning with People: The first 40 years of Tektronix. I rest my case. 73 de Fred.

They certainly are proud of their gear!
Their prices are, IMHO, about 2-3x what they should be.

Check your fly, Fred. Something ridiculous is hanging out.
I've never heard anybody say Tek was a "bad" company or made bad gear.
Tempramental, maybe, but not bad. But this day in time (since the book
came out) big corporations aren't run by the good guys like Warren K....

Could it be they don't want to do anymore service, perhaps it cheaper just
to replace those new off seas plastic cheap ones one under warrantee.
I called them about a Tek 2232 and someone on the other end got all pissed
off, said call GTE for service ?

Motorola originally named this logic family "ECLips" but had
to change it due to trademark infringment to "ECLinps".
The line was sold to On Semiconductor in the 1990's.
See www.onsemi.com.

I had quite the opposite result when I called them on an encoder failure on
my TDS-420a

They were very helpful, and the replacement encoder was surprisingly
inexpensive.
They took a few minutes to verify that we were ordering the right part,
because of an ambiguity in the part number, but it was resolved quickly.
The whole thing was less than $50 and I even got spare encoders at that
price, in case of a future failure.

Perhaps. However I know in some industries, the same thing is done to prevent something like this happening:

Original owner of functioning, well cared for unit sells it at a flea market etc.
New owner modifies/breaks unit, then sells it to 3rd owner
3rd owner is dissatisfied and blames manufacturer, perhaps with little effect, perhaps with significant damage to manufacturers reputation.

I know from first hand experience that this was the case with 2 well known 2 way radio companies. If you were caught sneaking a trade-in out of the path of the crusher, you got canned.

His description indicates that the circuit board (and
presumably everything on it) came out of a Heathkit
HW-16 transceiver. It was Heath's choice on tubes.

I've thought many times about doing the same thing
using the receiver section from an junked HW-16 that
I have in storage.

All prices are in US Funds.

QTY. Part # Unit Price Description
---- --------- ---------- -----------
OPTO.

125 TIL311 $7.00 ea. The TI TIL-311 is a Hexadecimal Dot
Matrix Display with integral TTL driver
electronics to accept, store & display
4-bit binary data, Epoxy package
(Note: This part wholesales at about $16.50 each)

8 TIL311A $7.00 ea. The TI TIL-311A is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Plastic package

10 DIS1417 $7.00 ea. The TI DIS-1417 is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Epoxy package

For a copy of the TIL311 Datasheet see:
http://www-s.ti.com/sc/ds/til311.pdf and it is mirrored at
http://umwnt1.physics.lsa.umich.edu/mttc/images/til311.pdf

275 Green LED $0.10 ea. Rectangular 5mm x 2mm face/lens
$17.50 per bag of 250 ($0.07 each) and

8,750 Red LED $0.10 ea. T1 3/4, 5mm Diameter or 0.2" Diameter
Sharp P/N: GL5PR4 (5mA at 1.9V)
$17.50 per bag of 250 ($0.07 each) and
$100 per box of 2000 ($0.05 each)

106 MAN6440 $0.95 ea. Dual Digit, Green 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 MAN- 6440 ($0.75 ea.)

85 FND6740 $0.95 ea. Dual Digit, Red 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 FND-6740 ($0.75 ea.)

TTL CHIPS, DIP Package

550 7407N $0.18 ea. $4.00 per tube of 25 ($0.16 each)
Hex Non-Inverted Buffer with
Open-Collector outputs

605 74ALS20AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Dual 4-Input Positive NAND Gates

240 74ALS27AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Triple 3-Input Positive NOR Gates

1350 74LS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

100 74ALS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

RESISTORS

55,000 100 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$15 per box of 5000 or
$100 for 50,000 pieces.

4,000 220 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 4000 or

4,000 680 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 4000 or

A pack of 100 resistors is $4 inclusive shipping to anywhere
in the US and Canada

e-mail: jrpart@excite.com

Minimum purchase $4 including postage.

No shipping is included in the above prices. To quote a
total including shipping, I require your full ZIP code or
postal code in addition to a list of what you are interested
in. Please specify the country for international orders
outside of North America. The shipping you will be quoted
is the cost of the postage stamp (plus insurance if requested).

The only part that I will ship for a total of $4 (by regular
mail) to anywhere in the US and Canada is a pack of 100
resistors.

All components are new. All semi-conductors are stored in
anti-static tubes/bags or on anti-static foam if you purchase
less than a tube/bag.

Offers on the lot are welcome. Keep in mind that I am looking
for a price below wholesale, but more than the commercial buyers
of surplus electronic parts are offering.

You'll never know before you have tried, and remember that Racal
solved a similar problem with their famous RA-17 series receivers
using a hacksaw to make a little mark in the chassis to stop unwanted
radiation from one point to another. Believe I've seen the application
of those carbonized foam used in the lids of boxes which were
definitely not microwave equipment

Such things are impossible to predict

It is also some definite requirement for the thickness of the walls to
act as screen on certain frequencies, as an example could be mentioned
that pcb laminates are not thick enough for good screening on 80m in
an application with two oscillators which need good screening to avoid
coupling to be used for third order IP measurements

Me too, but it was after many years of not being able to get them - read
the stories by Wayne Green and Byron Kretzman about the machines that
used to go to the landfill. Same with Motorola - a few hams spoiled it
for everyone by reselling 2-way radio gear back into commercial service
after they had "promised" (and signed waivers) that the equipment would
be used only for ham radio use and not resold into commercial service.

Sometimes it's just cheaper in the long run to dispose of gear than try
to support it and lose a potential new equipment sale.....

3411. TR751 Power Out and APC adjustments

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-12 03:01:46 UTC
From: John <jmort@despammed.com>
Message-ID: <botn8iggo1@newsg3.svr.pol.co.uk>
Source record: 31140

I have just got my TR751 working. (Kenwood 2m multimode transceiver)

Does anyone have details of the APC adjustment procedure? Also details of which pot controls power output in Hi power position. I am getting nearly 40 Watts out on FM in to 50 ohms whereas the spec says 25 Watts. I want to turn power out down so as not to stress the output brick.

Thanks

Bill, I've never worked for Tektronix. My personal oscilloscope is a
Philips 50 MHz dual-trace used demo unit bought at a fair deal from a
Philips representative in 1981. On the other hand, I've been very
much acquainted with their line of instruments since 1954 and can
say that their quality, maintainability, and holding-of-accuracy is
excellent. I can afford them for contract jobs...just can't afford them
for personal use.

The price of ALL electronics instruments has constantly gone up in
the last half century...the major reason probably in that the
performance and range and flexibility has also increased...which
leads to the various companies amortizing new instrument
development costs back to the buyers. Like TS for all those who
want high-performance goodies at Knight-Kit prices.

Jim: I built one years ago. Mine worked. It was one of my first
successful HB projects. It was great fun to get that thing to oscillate.
I'd set the freq counter aside and listen around the xtal freq with your
receiver. It may be oscillating faintly up or down a few khz from the freq
marked on the rock. And it will probably be too weak for the FS meter.
Good luck. Hang in there. 73 from London Bill M0HBR

As of last year, Motorola still did send their trade-ins to the crusher.
They did the same thing with engineering units. I can't tell you how many
XTS-3000s went to the crusher.

More than a "little mark" - a big cut, deliberately intended to
interrupt an unwanted current path through the chassis.

>
>Such things are impossible to predict
>
If you stop to think about it, such things often *can* be predicted...
or at least explained with the benefit of hindsight.

When we connect a signal from point A to point B, we often forget about
the return path through 'ground'. But every signal path must also have a
return path - that's why we call these things "circuits". Even if we
shield the signal conductor to provide a preferred return path, there
are still other return paths available in parallel with that, through
the box.

Return currents will divide between these paths according to the RF
impedance that each path presents (Ohm's law), so you will always get
some RF currents in the body of the box. The box is just another RF
conductor, and when currents flow through it, voltages will appear.

The key thing is to remember that there's no magic that makes the box a
perfect zero potential. For all us Sixties children: "'Ground' is a
delusion, Grasshopper."

Therefore in a complex project you will always get some interaction
between different stages. What's hard to predict is how much effect this
will have on overall performance.

The problem that plagued Racal was spurious receiver responses. Racal
was a startup company with a revolutionary all-band receiver concept...
but it involved several oscillators in different stages, that were
getting into the wrong parts of the receiver and causing "birdies". They
couldn't sell a single unit until that problem was fixed.

They had already gone to the huge expense of a diecast chassis divided
into many shielding compartments... and it wasn't working. Very soon,
the money would run out and Racal could cease to exist. Hence the

desperate solution with the hacksaw - and it saved the company. Legend has it that the prototype receiver (complete with saw cut) was on display in Reception for many years... maybe they shoulda kept the hacksaw too?

I once had a problem of this type with spurious responses from a receiver that was constructed in three (apparently) shielded diecast boxes with coax signal interconnections. The boxes were stacked side by side inside the case of the receiver. Remembering the Racal experience, something made me shove a piece of folded paper under one of the boxes, to insulate it from the receiver case. The spurs disappeared!

Looking further into this, the real problem was with the power interconnections between the boxes, which I'd been ignoring until then. RF was getting into the power rails, and contact between the boxes formed a ground loop. Unwanted signals were being transferred between the two boxes via this 'back channel'. With better bypassing of the power rails, it was possible to re-connect the boxes to the case of the receiver.

Thanks a lot for the info John. Have now adjusted power o/p as you suggest. Am I right in thinking that you have a TR-751 ? On SSB mode my 751 receiver background noise is very quiet although the RX is quite sensitive. What is the background noise on SSB mode like on your 751 ?

Does the service manual run to many pages ? Do you have a scanned copy by any chance ? I do have access to all the necessary test equipment in your list.

SO239/PL259 were used in the 60's for radio link equipment on 400MHz,
but it was a prosedure to connect the cables correctly.

I wouldn't choose such connector, my choice would be N-type or Spinner
for cables going out of the equipment, with a limited application of
BNC type. In fact BNC is just as bad as PL-259, and it is seldom
mentioned in AR groups, but rather intermittent above 1GHz. Suppose
most participants on the NG's operates only 2m FM? TNC is far better,
but I don't like to mix up with too many standards. PL259 are good
enough when already installed on proffesional equipment, and only
then.
Inside the equipment I would prefer conhex on lower frequencies and
BNC when impedance is important, SMA on SHF. Also have some equipment
with dezi-fix connectors, but I've never seen much comments on these,
not sure when they are 50 or 60 ohm type

Your analysis might be true, IF there was any continuity to typical management. Businesses that have been "doing the right thing" for 50 years can suddenly do bizarre things, often from bringing in a "breath of fresh air" in the form of a manager hired from competition, or, even worse, from some totally unrelated industry. Or the management level fills up with lawyers and bean counters. Got synergy?

Other things, like management loosing their collective nerve or direction, can also produce this effect. Remember Coke? For 90 plus years, brand leader with an unchanging formula. Then the data comes in from some market focus group, and we suddenly get New Coke!

BTW, this "news" about destroying obsolete products is very old news. Seems like more than 10 years ago, HP was doing this on 141-series analyzer mainframes. Come to think of it, HP ain't the old HP anymore, huh?

In this current time, NOTHING is as it used to be.. As the man pointed out with management, ideas, formulas and so on, it seems all of what "used to be" common sense has gone out the window. Nothing should come as a surprise in this day and age.
But, speaking of trashing items, I too know of a few companies that trash their items with no regard to future use, and so on.
This world is run by a whole different set of rules now and even they aren't set in stone. It is a shame to see such equipment still with some life to it demolished, but such is life. G.W.

IIRC HP broke into several different companies - the one that makes
computers absorbed Compaq (or was it the other way around) and the
one that makes printer stuff is the "new HP".

The one that made (from the start) and still makes some of the best
test equipment now has a new name.

It shudd'a been the other way around.

I need a new calibrator crystal for my Eddystone 770U Mk II. The specifications are in the manual but I need to know what "package" it is ... the manual states it is a "Style D". I suspect from the way the crystal holder looks that this might be a HC-48U ? Any help appreciated ?

I'm not sure what you mean by "APC adjustment procedure".
The complete transmitter adjustment covers two and a half pages and
requires a lot of test equipment. RF voltmeter, frequency counter,
power meter, DC voltmeter, linear detector, oscilloscope, spectrum
analyzer, and AF voltmeter to name most of them.

The power adjustment is the easy part.
Place the radio in front of you with the controls toward you.
Remove the top cover.
In the right rear you will find VR4, VR3, and VR7 close together
on the composite unit (TX) board. They form a triangle.
VR3 is the low power adjust
VR4 is the high power adjust
VR7 is the CW break in delay

Low power is supposed to be adjusted for 5 watts
High power is supposed to be adjusted for 27 watts

Power should be adjusted with the radio in CW mode.
A VHF capable 50 ohm dummy load must be used for the adjustment.

Be careful - there are three VR3 and two VR4 pots in the radio.

John

3430. New Home Brew Store

Newsgroup: rec.radio.amateur.homebrew

Greetings all,

This is a message to let you know about our new homebrewing web site :
http://www.brewityourselfers.com.

We have home brewing supplies, recipes, and information. It is a site
dedicated to the homebrewer, and everything that
the homebrewer needs. Be sure and check it out. If you have any
suggestions, they are appreciated, the more input the better.

Some of the features:

* Home Brewing supplies
http://www.brewityourselfers.com/docs/Products.php

* Home brew recipes
http://www.brewityourselfers.com/docs/recipes.php
- Order supplies based upon the recipe

* Keep your own home brewing recipe book
http://www.brewityourselfers.com/docs/Products.php
- Keep recipes privately, or publicly
- Keep private notes on recipes

* First time home brewer's instructions
http://www.brewityourselfers.com/docs/first beer home brew.php

* Beer calculator --http://www.brewityourselfers.com/docs/beer
calculator home brew.php
- Calculate Alcohol content
- Convert Balling and specific gravity
- Adjust specific gravity for temperature

Hope to see you there,

GandalftheStout
http://www.brewityourselfers.com

> John G3UGY

Yes I have a TR-751. In SSB mode, in the absence of a signal, there is considerable background noise if the squelch is off and the RF gain is at maximum. The squelch knob works in SSB mode. I recently had to replace both the volume and squelch pots in my TR-751 and my TR-851. I took one of the bad ones apart and found that the metal wiper had come loose from the plastic piece that supports it. If I had a surgeons hands I probably could have repaired it.

I have an original service manual. I don't have a scanned copy. The service manual is the equivalent of 94 8-1/2" x 11" pages. There are several double and triple fold out pages. Quite a few pages are taken up by the parts list, the schematics, and colored images of both sides of the circuit boards. The adjustment section is 12 pages. The circuit description is 12 pages. The element function description is 7 pages.

It looks like the manual may be available from

http://www.amateurmanuals.co.uk/

If not, I can probably scan at least the adjustment section for you. You can get my email address by looking up my call sign at

http://www.qrz.com

Pin one should be marked by a dot on the top of the case, or a
different color glass seal on the "pin one" lead.

On a "real" basis -- adjusted for inflation -- the cost of instruments has been going down. a TEK7704a with 4 plug-ins cost as much as a car when it was introduced -- today you can get same performance (well actually more since you have FFT and math) in a TDS3034 for 1/2 the price of a car.

Power level?

Low end: use a brick.

High end: look in just about any reference published in
the last 25 years, including the UHF/Microwave Projects
Book and the VHF/UHF DX Book.

Most novice designers get burned somewhere along the line by failure to realize what Ian is describing -- that all amplifiers are differential amplifiers, and calling one of the inputs "ground" doesn't impart magic properties. Once that lesson has been learned (alas, usually the hard way), the probability of making circuits work as designed increases dramatically.

Even so, though, a surprise sometimes comes along at the last minute. I know of one expensive, high quality test instrument that had a ground path broken at the last minute because of ground current that was induced in the signal path by the field from the display CRT deflection yoke. Forewarned, I discovered 100 mA of induced current in the shield of a multi-turn delay line from the same source, in an instrument in whose design I was participating. Simply soldering the turns of semi-rigid coax together reduced the effective transformer secondary to one turn from 20 or so, making it possible to reduce the coupling and its effect to an acceptable level by other means.

But I remember that shortly after I went to work at Tektronix, I was in the main lobby admiring the example of the first oscilloscope model produced by that company, which was on display there. Its success and the reputation it gathered as a quality test instrument was instrumental in launching the company. It had two chassis, one above the other, supported by four L - cross section aluminum legs between the chassis. One of those four legs had very neatly been cut, leaving a small gap. A sturdy piece of phenolic was mounted between the gapped ends, again very neatly, with countersunk flathead screws. I remember that seeing this gave me a good feeling that ground currents could be a problem for the best of 'em.

The 'scope in the lobby was a production model, but somewhere, I'm sure, there was a prototype much like the Racal device -- with a hacksaw cut across the leg.

3446. AM receiver filter characteristics

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-13 21:15:42 UTC

Message-ID: <bp0s9j$p1q$1@news.oregonstate.edu>
Source record: 31063

For a direct conversion AM receiver for the commercial broadcast band (550-1710kHz), could someone suggest appropriate low pass filter specifications? I'm looking at a standard (cheap) superhet receiver with a two stage transformer coupled IF amplifier/filter, and then end up with a bandwidth of +/3kHz (around 455kHz). Hence, this would be equivalent to a 4th order filter with a corner frequency of 3kHz -- correct? I was thinking I'd need somewhat more aggressive (but wider) filtering than this (more like an 8th order filter with a corner at 5kHz).

If a commercial AM station is transmitting at, say, 550kHz, is it a safe bet that the FCC wouldn't have stuck another reasonably powerful station at 560kHz, the next 'channel', in the same geographic location? That they'd at least wait until 570kHz to do so? Historically I would think they'd have had to do so in order to allow these simple IF transformer coupled amps/filters to perform satisfactorily.

Thanks,
---Joel Kolstad

Would it be possible, though not necessarily practical, to make a reciever for the modern FM broadcast band, using only pre-WWII tube technology? I know they had FM on a lower frequency band at that time. What sorts of tubes could one use from the 1930's to make a reciever that could tune in the modern FM band? I'm sure I wont actually attempt such a thing, especially any time soon, but just wondered how difficult it might be. Are there any schematics or construction articles from the late 30's about making FM radios that might be adapted over to the new FM band?

just curious,

Dave

There is no problem doing that. Realize that the 'modern' miniature tubes of the 1950s that were used to make FM tuners are internally identical to the old tubes from the 1930s.

You use a 6K7 instead of a 6SG7 for instance. Or if you want to go even older, a 36 I think. A 27 instead of a 6AT6 (triode section).

The lead lengths are longer and might require a bit more care in layout but it should be okay. Just look at the Hallicrafters S-27 for some ideas.

Bob

To my simple mind, the technology is essentially the same between prewar FM and "new" FM. You would change some coils & whatnot, primarily in the front end (experts, chime in here as usual to correct my habitual blunders :-), to receive and decode the same kind of signal, only in a different frequency band. You would also want a dipole antenna of slightly different size than what's used now. Otherwise, I see nothing to prevent you from building a "new FM" receiver using prewar components.

Phil

You won't find stations closer than 40 (sometimes 30) kHz "in the same town". Rimshot stations are often closer spaced. However at night you have long distance ionospheric propagation. At night, most stations are only protected to the contour where their signal and the signal 10 kHz away are EQUAL. What signal level this is differs by class of station and also stations can accept worse. IIRC, some may not be protected beyond their 25 mV/m contour at night. 2.5 or 5 mV/m is more common. Pretty much all bets are off for stations on the graveyard channels of 1230, 1240, 1340, 1400, 1450 and 1490.

The FCC never allocated on the basis of the worst possible receiver. Super el cheapo radios may well have trouble within the "interference-free" contour.

About half the present frequency.

> What sorts of
> tubes could one use from the 1930's to make a reciever that could tune in
> the modern FM band?

It was something of an effort for them to reach even 50 MHz. Tubes like the 6AC7 would have some gain. No one building entertainment radios had heard of noise figure, so their sensitivity was terrible by post-war standards. One of the most popular and best prewar tuners was the GE JFM-90. Its front end was two pentode mixers, one after the other. Its noise figure must have been astronomical. At least 20 or 30 dB worse than today's radios.

> I'm sure I wont actually attempt such a thing,
> especially any time soon, but just wondered how difficult it might be.

The main problem would be the large cpapacitance in the big octal tubes. IIRC, the first all-glass 7-pin miniature tubes didn't appear until 1940-41, the 9001, 9002, and 9003. You could build a fair set with them given today's knowledge.

> Are
> there any schematics or construction articles from the late 30's about
> making FM radios that might be adapted over to the new FM band?

The new band wasn't chosen until about the end of WW2, so prewar sets weren't designed with it in mind. There were only a dozen or so operating FM stations before WW2, so there wasn't a lot of discussion of the technology. I have/had a just-prewar book of build-it-yourself radios put out by Popular Science (I think) which had an FM set. It was pretty complicated. They hadn't learned how to cut corners. The IF in old-band sets was 4.3 MHz, not today's 10.7 MHz. The lower frequency allowed better gain with the tubes at hand, and the narrower FM band didn't result in inband images. Modulation, etc, was the same as today.

Some of old VHF Hallicrafters sets used the acorn 954, 955, etc, tubes. They would do ok at 100 MHz, but were exotic and never used in consumer equipment.

So basically if I could somehow use 30's tubes to tune to 100 MHz more or less, all I would need to do then is to add a suitable FM detector and bingo? Hmm I think I will need to do a lot more research on this one....

You should be able to get good performance with acorn tubes in the front
end. Acorn tubes pre-date octals, if I recall.

The prewar FM setup not only used a different band, but also a different
audio pre-emphesis. 100us as compared to the current 75us.

Different pre-emphasis is hardly a big deal, the important thing is that
the only significant difference was the frequency band used. The FM
deviation was the same for the pre war and the post war systems, so a pre
war IF strip and detector would work on the post war band, the only
potential problem being image responses due to the lower IF frequency used
pre war.

Articles I have seen about early attempts at VHF talked about removing the tube bases to reduce lead inductance but gain was still very low, even around 50 MHz. The early, hand made tubes used widely spaced elements that didn't perform very well at higher frequencies. Remember the old "Let the hams have 160 meters an up because its useless? It was, because there was nothing available at the time to make use of higher frequencies. Remember too, that early RADAR was at lower than optimum frequencies, as well. The 15E was an early RADAR transmitter tube that pushed the limits of the day. If 100 MHz or high band VHF was reasonable technology at the start of WWII you would have seen a lot of equipment surplus for those bands, rather than the HF band.

Yep. But the original poster might as well take the difference into account. Also, I think a 10.7 Mc IF strip would still be allowed under a pre-war tube technology stipulation.

Hey Brian, have you ever tried adding Beano to the wort? Sounds crazy, but apparently it is similar to what the Japanese use to make their "dry" beers. the enzymes ferment out things that would otherwise not.. I don't know if the Beano would fulfill it's original purpose or not! 8^)

I'm a homebrewer and a homebrewer, too.

I predict a batch of "Firebottle" beer coming up. Maybe something with
Habañero peppers?

As I recall, Armstrong invented and patented the FM radio before WWII. If I'm correct, his patent should show a schematic of the circuit he used. It's probably still available from the patent office.

I suppose you could brew up some "BPL" (boiled-pepper lager), but
what's the sense in making a beer which drowns out all the flavors in
your food and makes it impossible for you to talk?

Focus on the front end. Once you get to the IF, then my Emerson 460 pre
war set
would have the same technology as your "what if" set. I think acorn
tubes were pre war,
and were designed for VHF service. 2 or 3 such tubes (one RF amp,
another local
osc, and the 3rd the mixer) should make a good 100MHz front end. The
above Emerson
had an IF around 4 or was it 8 MHz, used octal tubes like 6SG7 and 6SH7
and a 6H6
for an FM detector.

FM back then was on frequencies around 25MHz for experiments. Ordinary
higher frequency HF SW front ends would have sufficed, with a higher
frequency IF strip. Today hams have a
small 10 meter sub-band for FM somewhere around 29MHz. Later a
broadcast band
from about 41 to 50MHz was set up. See
http://members.aol.com/jeff560/jeff.html for more FM history.

>especially any time soon, but just wondered how difficult it might be. Are
>there any schematics or construction articles from the late 30's about
>making FM radios that might be adapted over to the new FM band?

I doubt you will find much in amateur radio periodicals. They do
exist in various corporate libraries, though, since the VHF and up
radios were being pioneered in the late 1930s, some of the first being
police mobile radios. Those would evolve into the SCR-300 backpack
"walkie-talkie" of WW2 Army use and those shiny chrome button
channel select "tank radios" used mobile back then. The AN/TRC-1
through TRC-4 of WW2 times was low VHF (70 to 90 MHz) using
octal base tubes, PM with lots of multiplier stages following a MF
crystal oscillator.

Of course there are lead length problems with big bases as well as
the electrode connecting leads within bigger tube envelopes. What
most folks don't consider is the electron transit time within the tube
structure. That is slower than the speed of light (don't have an exact
value handy) and will cause a significant phase change between
grid input and plate output at VHF and above. The "lighthouse" triode
structure (ultimate may be the 2C39) has terribly short tube electrode
spacings allowing operation on up to 2.5 GHz...very quick electron
transit time internally.

Note: Klystrons and magnetrons go much higher in frequency. In the
case of the klystron, an integral tuned cavity structure is an absolute
requirement for operation. The magnetron depends upon both the
diode spacing (it is only a diode) and the magnetic field and the voltage
and the output tuned cavity structure to oscillate at X-band.

Anyone can play games with old, big tubes used at low-VHF and
arrange all kinds of neat tuned circuits to work with long leads and the
long electron transit time. Problem is, the amount of extra components
isn't really worth it. Whenever a tube has to be replaced (happened
often due to filament technology still lagging) then you would need to
do a humongous amount of retuning. About the only thing workable
for the oldie tubes is the distributed amplifier wherein LOTS of tubes
were arranged along tapped delay lines for grid inputs and plate

outputs. [the Tektronix 54x series of oscilloscopes uses such an arrangment as the final CRT voltage driver for vertical deflection plates] Very good as a space heater for a residence in winter...

The electron transit time thing is akin to a low f_sub_t in transistors. Such low f_sub_t bipolars might be okay on low HF but their characteristics don't allow good amplification or easy oscillation at VHF and higher. Some of the newer SiGe bipolars have f_sub_ts in the tens of GHz range.

Electron transit time depends on filament-cathode temperature, tube geometry (and element spacings), and accelerating potential (screen and plate quiescent voltage). There's no precise value that fits all tubes. To view what did work at 70-90 MHz, find an old AN/TRC-1 Technical Manual and see which octal base tubes were used there. The transmitter box final amplifier was an 829, good for about 50 W, but not an octal base tube.

Len Anderson
retired (from regular hours) electronic engineer person
[and caretaker of TRC-1s and TRC-8s a half century ago, among other tube-based radios]

3472. Newbie qrp homebrew transmitter; another question

It's me again. To refresh your memory, I'm building the "Dourg DeMaw classic" transmitter as shown in the June 1967 QST. Details are at:

http://www.kcnet.com/~oyster/transmitter/transmitter.html

Things are working much better. I'm nearly ready to go back on the air with it for real. I did a test, separating transmitter and receiver by several miles, with identical dipoles at each end, and my helper said that she received a nice strong signal at the fundamental (7125 kHz). The problem is, she also heard a signal about half as strong at a subharmonic (3562 kHz). Does anybody out there know what might typically cause this to happen with a transmitter like mine? It didn't occur to me to try a random wire at the receiving end as a comparison. My receiver is an Icom R71A.

My homebrew lowpass filter is working. It's in its own box with SO-232 connectors. I've verified that it prevents TVI, and also silences any emissions at 2x, 3x, and 4x the fundamental. Without it, I get a lot of TVI on a TV at home.

But I want to get rid of that 3562 kHz signal, which is right in the 80 meter band. I've had success so far by just experimenting with rerouting ground connections and making the layout more efficient, so I feel that the answer might be in that direction. Any advice would be welcome. Please have a look at my website. Thanks!

Flippin' 'eck! 22pH is probably less than the stray inductance of the
device itself!
Actually, I can never rememeber these codings either. I believe it's
22uH but if someone more knowledgable can post the key to the inductor
multipliers here it would be very helpful!

This tx of yours is fixed frequency, right? If so, why not just
knock-up a simple notch filter for 3562? Or even a high pass? I know
it's not establishing the cause of the sproggie, but at least it's a
quick expedient to stop you confusing the chaps on 80m!

You're going to have a bit of trouble with the older tubes. They had long skinny leads leading down to those high-capacitance octal bases.

Hams were able to get things going up around 140Mc/s, but it was mainly super-regen receivers.

If you want to try it, I'd find the smallest dual-triodes of that era, say 6SN7's, and make up at least one maybe two cascode Rf amplifier stages, then another triode mixer, then maybe another cascode first IF amp. By then you should have enough signal to start using old pentodes as IF amplifiers. If localts are allowed, the 7F7 IIRC is probably a much lower capacitance dual-triode.

I do recall one post-war Sparton FM set that used a 6AC7 as the RF amplifier, a 7Q7 (loctal 6SA7) as the osc/mixer, then three 6SJ7's for IF amplifiers and limiters. Worked surprisingly well.

isn't it true that the older stuff is built like a battleship and
isn't as proprietary and can be repaired with user obtainable parts?
I always heard tek for scopes and hp for analyzers. Any thoughts on
that?

My experience is that HP scopes are OK-to-great, while Tek scopes
are excellent-to-superb. Similarly, HP generators and analyzers are
excellent-to-superb, while OK-to-great.

There are other manufacturers that make excellent-to-superb hardware,
such as Fluke.

The repair depot in Washington DC has one old guy who likes working on the
older gear, and has some limited parts supply for them. Last year he spent
an awful lot of time getting the 100V supply on my 610 video monitor working
reliably, and I can strongly recommend the DC folks.

Could this bird come from the kind of crystal used ? I guess a better pass band filter would solve the problem at the oscillator.

I don't think filtering the spur is a good answer; it's sort of brute force. Better to find the cause and eliminate it.

If the oscillator is on 40 meters it would be strange to find a subharmonic. On the other hand, if it's on 80 and there is a doubler, that could explain it. (I haven't looked at the diagram.)

Assuming the oscillator is on 40, the 80 meter spur might occur because the oscillator is squegging, or cutting out, on alternate cycles. Or, if it's a crystal, the crystal might be fractured.

If the oscillator is on 80, reduce its amplitude and investigate the Q of the succeeding circuits.

An excellent approach would be to look at the waveforms with an oscilloscope to see just what's going on there.

The saddest problems I have found with the HP gear is purely their own fault. When they made the horizontal timing knobs for their 80's vintage scopes, they made them out of plastic, and carved large slots in the space between the outer part you turn with your fingers and the inner part that turns the knob. This left very little plastic to take the torque of turning the knob. Once they break there is no easy way of repairing them.

The other big problem is their use of delrin gears with aluminum hubs just about everywhere. And after 15 years, they are all broken. The HP8640B is built like a tank, but everyone I have ever had came with several gears that had split due to shrinkage.

Roy-

Armstrong's classic paper "A Method of Reducing Disturbances in Radio Signaling by a System of Frequency Modulation" was published in 1936 in the November Proc. IRE. (The paper was presented in a demonstration at the Nov 1935 IRE New York meeting.)

His field work started 1934, at 44 MHz, with a 2KW 44 MHz transmitter on the Empire State Building shortly thereafter (the article is a bit vague on the timing of this part of his operation). (Also, the frequency was changed to 41 MHz at some point during the trials.)

Armstrong also notes the problem with receiver RF amplifiers at this frequency and thanks RCA for its provision of experimental VHF receiving tubes.

His detector circuit looks like a conventional discriminator to me; two detectors each coupled to a tuned circuit with the outputs summed. One detector gives + and the other a - output. One tuned circuit resonates on the high side of the IF passband the the other on the low side. Each detector fed by an independent buffer amplifier. The receiver was a double conversion, with the first IF at 6 MHz and the second IF (and detection) at 400 KHz and a passband of 150 KHz.

That sounds just like the knobs used in the HT 32, 33, and SX101
series. They have a very thin flange, or lip around the front that is
very fragile. I saw one on e-bay a couple days ago that was described
as excellent, yet it had at least two sections of that lip missing.

But Delrin is very easy to machine.
Also unless the gears are of a very odd size (most are spur gears or a
pair of 45 degree bevel gears) that can be replaced with something
more modern and durable.

I do like a lot of the new, lighter weight gear as I have a bad back.
(Probably from man handling that old stuff that takes two good size
men to load it into a trailer)

What specs do you want, and how much do you want to spend? The HP 141T series is great for technically-inclined hams. Very maintainable, very reliable once you understand its quirks, very competitive performance... and very big and heavy. Typically $1K or less on eBay for a working outfit.

Tek's 492-497 series are also excellent analyzers. Newer and much more portable than the 141T series, but still easily maintainable (via parts units and aftermarket suppliers, not through Tek). Quite a bit more expensive in most cases. $2K - $7K depending on model and options.

HP 8560-series analyzers are also very nice; I have no personal experience with these, though. Stay away from the cheaper (8557/8/9) HP units. Tek's older 491 is probably also best avoided in favor of the 141T line (this is probably where the saying "HP for analyzers" came from.)

Tek analyzers from the 2780 series should also be avoided by most users. They are still extremely expensive ($7K and up), and like the older 490/2750 analyzers no parts or manuals can be ordered from Tek anymore. However, unlike the 490/2750 units, they can be calibrated only with special PC-based configurations connected to specific test sources via GPIB and running obsolete software. Worse, Tek supported them only via module exchange, never releasing any component-level schematics. These are very powerful instruments, but keeping a 2782 or 2784 running nowadays would be a serious, ongoing research project in itself. These were symptomatic of the "bean-counter" generation at Tek, where customer needs were considered secondary to high-priced, proprietary product support and finite market lifetime.

I heard someone on the test-equipment reflector (http://www.qth.net) was
going to fabricate some replacement 8640B gears out of metal. You might
check with that list to see if it ever happened.

if she has received the signal across the town, then you are putting out a pretty strong sub-harmonic. a couple of things have to be checked up:

1) are u sure that the signal is actually due to the crystal? it might be that the oscillator is freely running on its own. to check that, test that the signal is stable, if u move ur hand around the coils or touch them, the signal should not shift its frequency. if it does that, then the crystal is not really a part of the oscillation.

2) if you have figured out that the crystal is oscillating properly, next, you might have mistuned your PA to 3.5MHz instead of 7MHz. Try retuning the PA, disconnect the antenna from the receiver attach a foot of wire to the output of the tx and tune the tx for maximum output on 7MHz. Then switch the rx to 3.5MHz and see if you can 'tune out' the 3.5MHz trace.

these are quick fixes. the larger problem that you are faced with really is that you don't exactly know what is going on. the above two solutions are based on diagnosing the problem emperically.

what you really need is a wavemeter. If you have another variable cap lying around, it might be a good idea to hook one up. It will serve you for years. It takes about 4 components to wire it up. You can caliberate it easily using a regular TX for 3.5 and 7. Now you can couple the wavemeter to each of your TX coils and tune it to the correct frequency.

if we are to assume that the crystal is actually 7MHz, i see no way that it can give sub-harmonics in a proper design. the only culprit could be the tuned circuits.

I recently brewed up a small portable NBFM tranceiver for the local ham group. Smallness and low cost were a requirement. My initial design which is working well is based on an 18MHz crystal that i multiply in balanced doublers three times over to 144MHz (using two transistors in push-pull at each stage) followed by a 500mW 2N3866 PA. I have found that without a high bandwidth oscilloscope (I used a tek 465) it is impossible to correctly align the tx. I am now considering switching to a scheme where i can run a VCO at 144MHz directly and lock it to a lower fundamental crystal. i can do this by:
a) injection locking the VCO with the a crystal oscillator. I have seen almost no use of this method (EMRFD just mentions it in one line) in amateur literature. my last post on this topic went unanswered last week.
b) using a simple first order PLL. is there a way to simplify this? the cost of a PLL IC or even an SBL mixer would be too high.
c) use an overtone directly on 144MHz (9th overtone in a butler config) and phase modulate its output. Any pointers to a phase modulator operating at VHF?

Mike, we need to get together at Dayton04 and bring some samples. My
smallest sample size is a 3 gallon corny keg.

Brian

Sort of. Amylase enzyme during mash, temp not to excede 140F. Half hour rest.

how about a 8569b ? some guy has one on ebay now for about $3,000.00......i might pull the trigger on that one.....I would be using it for hf work. I was considering a 141t from tucker . it cost more but at least you know it works. i was going to get the 8552b and 8553b plugins with it. then you have to round up the connecting cables and manuals for them. comments? oh by the way i have read good things about the hp 8569b's. if they work.

> what is a good spectrum analyzer to have for a home shop in your
> opinion, and also what is a good scope to have and do you have to
> break the bank on this stuff? thanks.

A tek 7000 mainframe is my spectrum analyzer, and backup scope.
I have a 7L5 plugin for 0-5MHz, and 7L13 for 0.1 to 1800 MHz
I also have the companion tracking generator.

This stuff was all aquired piecemeal at hamfests, and in total, probably set me back <$1k.
I've had it for (eek!) 13 years!

The 7000 series is getting long in the tooth, but there's a ton of plugins out there cheap, and they are very nice instruments.

Generally, get the best scope you can afford, and "give till it hurts". :)
My current scope is a TDS-420 4 channel DSO. It wasn't cheap, except in relative terms, but it's my main tool for earning a living, and I wouldn't want to work with less.

Depending on what you want to do with it, you might be ok with a 100 or even 60 MHz non-storage analog scope. You want the bandwidth to be >> the frequency you'll be working at. Assuming 11M applications, I'd say 60 would be marginal, 100 definitely better.

Also, GET GOOD PROBES! I just re-probed at Dayton this year, I think I spent $800 or so on probes. I got two sets of very nice probes (8 probes total) plus a set of lesser quality "everyday" probes that I use when I'm not really pushing the limits. Save the good ones for when it matters.

Some old BNC cable with clipleads will work at audio, but you wouldn't want to debug a switching power supply with it!

3501. Wire dispensing ideas wanted

Newsgroup: rec.radio.amateur.homebrew

First off, beautiful job!

Can you put a dummy load across L2, leaving the amp out
of the circuit, and still hear the 3562? If you don't,
but can hear the 7125, the trouble would be in the amp.
I should think you can try that using the R71A and won't
need the miles of separation.

But - I think the problem may be RF getting into the power
supply. If you can power it from a 12 volt battery and
it doesn't create that 3562, that proves it.

Either way, you do need to change the design. The old classic ran off a battery. You're using a power supply, and there is a direct path for the RF to enter the supply. Add a choke between pin 1 of the power supply connector and the junction of the key and the tune/operate switch. That way, RF can't flow into the supply. A 1000uH choke would have 2*pi*3.562*1000 (~223K) ohms reactance at 3.562. If there is not enough room in the rig for a 1000uH of sufficient current, you could still get over 70 K ohms reactance from a 330 uH at about half the physical size. You could also add a .1 uf to gnd across the junction of the choke and pin 1. Those values aren't critical - you could use a larger choke for even greater isolation, and a .01 if you don't have a .1 You do want a choke that will carry the current. A 500 mA choke would be more than enough for that. Your transmitter probably draws around 300 mA. You can get a 1000uH, 800 mA choke from Mouser for 85 cents or a smaller 330 uH 500 mA for 80 cents.

My guess is that the 8569b would be a very passable unit. Its specs seem competitive with an optioned-out Tek 492 in most respects, except that it only goes down to 10 MHz (perhaps there's an underrange capability that lets it see lower frequencies?) That might be a concern if you're going to be using it mostly for HF work.

I see that there's some modern GPIB software for it at www.febo.com, which is VERY good to have. (I've written my own for the Tek 49x analyzers, but it's never been tested on the HP jobs.)

But since I've never actually played with an 8560-series model, I can't speak with any authority. Maybe someone who owns one will pipe up.

The 141Ts at Tucker seem like a pretty good deal. I believe they all come with new CRTs. I personally like to buy broken models on eBay and fix them up. It's cheaper, you get really familiar with the gear inside and out, and you always have spare parts on hand. But that strategy isn't for everybody.

How about putting all the spools on a rod mounted at the back of the bench, with two pieces of foam mounted on two pieces of wood so as to grip the free ends? You could also use foam to act as a brake on the spools.

Leon

As I have HP-141's, an HP-8569, an 8566B and an 8562A, let me drop a few
comments here.

The 141's are the best deal for a hobbyist. You can acquire the slightly
better 8552B IF section, and then get only the RF plug-in that suits your
needs (an 8556, with it's built-in tracking generator, for a few Hz to 300
kHz, or an 8555, for 10 MHz through umpteen GHz, assuming you also get the
external mixers). Unfortunately, by the time a hobbyist gets one of these,
it has been abused and neglected by its last commercial owner. CRT burns are

common, and the flood-gun analog memory may be very quirky. For an advanced hobbyist, either get an associated Polaroid scope camera, or build your own camera hood. You can capture a lot of transient things that way, and you can scan the pixs to input into your computer. Also, HP made a line of oscilloscope plug-ins that fit the 141 mainframe, so you can use the 141 as a multi-channel analog memory oscilloscope too. 141's are a pain in two ways; first, you have to externally store extra plug-ins, and secondly, the hard side handles make carrying one a painful experience beyond about 50 feet. Also, you tend to injure your fingertips sliding those bulky plug-ins in and out past the big metal front handles. The 141 may also be the last of the hobbyist repairable analyzers; newer analyzers use proprietary chips and are built too dense to let you get fingers and probes into them.

The 8562A is old (1987) but a superb analyzer, 1 kHz to 18 GHz, all digital and synthesized. This will do everything you want, except drive a parallel or RS-232 printer directly. If you're smart enough to talk to it by IEEE-488, then you can do everything through the computer. Other 856x series units have lesser capabilities, but are still great analyzers, and just might be priced low enough for a very serious hobbyist. Also, the HP-859x series are very good, although some have odd frequency, memory and IO capabilities. All 856x & 859x series units are one-man portables, until your knuckles turn white and numb.

The 8569 is, in my opinion, a transitional beast between the analog and digital worlds. It's not as stable and simple as the 8562A, although it's a leap above the 141. Since it's wide, it's also awkward to carry using it's handle. I'm not much of a fan of the 8569.

The 8566B is HP's top-of-the-line analyzer. They threw down the benchmark for everyone else to try to meet. Mine is customized a bit, covering 20 Hz to 22 GHz, and with an external tracking pre-selector, optional detectors, programmable attenuators, RF path switching and low-noise pre-amps. My company has a number of somewhat more plain-vanilla 8566B's and 8566A's. There isn't anything I need to do that these units fall short of (uhh, with the help of some external IEEE-488 linked computers). OTOH, these are now obsolete, non-supported by Agilent, and need two guys to carry one. Mine is in a 60" tall dedicated rack. Typical used price is around $20k.

Most companies will be better served with one of Agilent's newer EPA or SPA analyzers. Anritsu and Rohde & Schwartz are also making fine analyzers. IIRC, Leader makes an analyzer that a hobbyist may aspire to affording.

I would say that a 141 is still the best hobbyist choice. A company needs to be sure that they get a usable item for their money, so buying on eBay is a gamble. A company should buy from some place like Tucker, where they get a warranty backed by a reputable source. Yeah, it initially costs more. But it's a lot safer than having to try to repair an analyzer when you need that analyzer to do the real work of your company. A hobbyist can afford to spend 50 to 100 hours to get something going; in a business environment, where the clock is always ticking, that's unacceptable.

I am looking for a gsm front-end, from antenna to I/Q demodulator output.
I need schematic, pcb layout and eventual prototype behind reasonable remuneration.

Most likely 22 micro Henries or possibly 220 micro Henries.

What would a 7Mhz waveform look like with a 3.5 sub-harmonic say 6 db
down? Does it display as two seperate, distinct waveforms or one
distorted one?

See the other suggestion.

Also, look at what professional electricians do, especially on
industrial jobs. They have a portable cart with the various wires
mounted.

There are commercial things available for this. Even if you make your
own, look at the premade ones first for ideas.

Happy trails,

Gertch used injection lock for years on their frequency meters. Had several good papers on the operation. I used a 100 kc xtal to "Jam" lock the LO on FM tuners for years in My frequency measuring service. Back when stations subscribed to a service on a monthly basis. Basicly I have divided down to 10 kc then "Jam" locked LO's at the broadcast band also. Regards, Sparks Broadcast Consultant

didn't the 141t's come out in the late 60's? I believe I read somewhere that the hp 8566b came out in 1995 and cost around $75,000 new, and like you stated I have read that it is the best spectrum analyzer ever built. I see them for about $10,000.00 to $12,000.00 starting on ebay but I would have some serious problems laying out that kind of money for a item on ebay. Thanks for the info. For all I know the 141t might serve my purposes just fine. I will look and see if tucker has one of those 8562a's though.

wow! I just looked at the tucker catalogue and the 8562a's are going
for $17,000.00. Looks like they don't want to give that one away
either. Seems like if you want a nice analyzer for your home shop you
had better go out and get yourself a home equity loan because you are
going to need it...

do you know anything about the hp 180t series mainframes with assorted
plugins? They have some of those also.

> i keep setting my heathkit cantenna on fire!!!

You might think about some additional cooling for the cantenna. What I'm thinking is to get a heat exchanger, pump the coolant from the cantenna through it with a small circulating pump, and back into the cantenna. You can probably use an automobile heater core for the heat exchanger, and an automobile blower to cool the heater core. You should be able to find those at good junkyard. You should find circulating pumps from many surplus dealers on the net, such as http://www.surplussales.com, http://www.herbach.com, http://www.surpluscenter.com and others.
ISTR that the cantenna is rated for 100W, but don't remember if it's continuous or not. But the additional cooling should certainly boost the power dissipation capabilities significantly.

It is 22uh

Look it as if it was a resistor but instead of ohms you express it in microhenrys

Red red black is 22ohms so your inductor is 22uh

The multipliers are
Brown 10
Black 1
Gold 0.1
Silver 0.01

So if the colors was red red gold then it would be 2.2uh and so on

It took me weeks to realize that I was reading an 22uh inductor as 220uh

Thanasis

ISTR a simple LC oscillator that, when coupled to a frequency counter,
enabled unknown/dubious inductors to be classified when oscillating
with a known Capacitor. Where did I see it?.

IIRC, the 180 mainframe was a different form-factor than the 141. The 180
stacked up a bit more like a big oscilloscope.

One thing I've used ... if you simply put the inductor in series with a resistor, and then put RF across it, you can then measure the voltage drops across the resistor and the inductor with your RF probe and from there calculate the inductance ... or capacitance for that matter.

The oscillator idea sounds a little more convenient, once you built up the oscillator, with a few capacitance choices to get the resonance on the right planet.

A 140 series, with a round face CRT came out in the early 70's. The 141,
with a rectangular face, hit around 1975. The 8566 was around 1991, IIRC.

Unless you get extraordinarily lucky (and when does that ever happen), all
but the 141 series is priced beyond the hobbyist. Maybe some of those 8562's
or 859x's will be still working in 5 years or so when they hit the surplus
market. Till then, hobbyists are still pretty much in the analog SA world.

Hi gang,

I've never had a lot of luck with GDMs for some reason. Even with a decent meter, it seems such a drag tuning across such a vast range looking for a tiny, easily-missed dip which you have to screw out of the meter by forcing the sensing coil so far into the circuit concerned you practically break the circuit board. Am I alone in finding this potentially invaluable device practically useless in practice? Is there a more viable alternative?

Source record: 31042

If a Heath Cantenna is overheating all that much that indicates that it is being used at well beyond its rated power. Added cooling is not necessarily a solution. The stress on the resistor comes from thermal sources as well as electrical sources. Even with "adequate" cooling, if you exceed the current handling capability of the non-inductive resistor it will shorten its life.

An alternative solution is not to use a Cantenna at all. Use an inductive resistor with an adequate rating and an antenna tuner to tune out the reactance. Another approach is to use a 40m antenna as a dummy load. Wait until evening, tune up on top of a foreign broadcast station, and use that for testing purposes.

The 141 weighs a ton, but it's rock solid stable, it sells for reasonable money at hamfests, and it's not that hard to get repaired.

Also, I think the Singer spectrum analyzers of that era are underrated and sell for very low sums considering how good they are. When I first used one, I was amazed at how birdie-free it was (although admittedly this was 30 years ago, and all of our standards for birdies are a bit higher).

>Unless you get extraordinarily lucky (and when does that ever happen), all

You know, I like the analogue SA gear. I like analogue scopes too.

I see a lot of wideband hand-held receivers like the Icom R10, some of which have crude LCD panadaptor displays. Has anyone used any of these as cheap spectrum analyzers? If so, what is the one that will give me the best resolution possible? I don't much care about the front end sensitivity. I can live with some serious limitations in order to have something I can carry in my pocket.

It would be very nice to have a spectrum analyzer I can carry up to the top of the tower with me to poke around at the head amps before taking the whole thing down.

Have a look at the manufacturers of GSM chipsets like Analog Devices,
Motorola, Texas Instruments, Siemens. They often have reference designs and
evaluation boards.

major respects to the previous analog versions.

Translate the dynamic range ie noise to max signal for a fair analog
scope and represent it in bits ; translates to 24bits or so with 100+MHz
bw cant do that with digital only 12 bits or so!!

Ive re recently had access to all types and demonstrated that to see a
.1mV 200MHz parasitic oscillation on a 10V 10MHz sin wave cant be done
on a modern scope (have to use analog spectrum analyser) but easy on a
good analog scope .
Cheap Analog still available from Japan we are being forced in that
direction bt Tech and Agilent/HP

First rule is to get a good dip meter- the stuff made for the amateur community is very poor- the Eicos, Heath Millen etc. Pick up a Measurments model 59. With this meter you can take a 1/2 wave wire- say at 2M and hold the meter a couple inches from the center and see a huge dip. Other meters don't even respond when held to the wire. Dips on conventional L-C circuits can easily be full scale.

It is kind of hard to get the proper coupling on PCB style coils.
You may have to use a link coupling system (came with some
of the Millens); also solid state circuits can have fairly low Q
circuits, again making it hard to see the dip.

Those were intended for larger tube circuit designs, not PCB
based gear.

Pete

No, there is no person so named. Would you prefer that he had used the sort of expletives that those symbols generally represent? Have you never seen profanity annotated that way (think: comic strip)? The 'Sanford & Son' reference was made by the service rep, apparently referring to the gall of the OP, for wasting the rep's valuable time asking for information about equipment that he (the rep) considered to be nothing but junk (you'll recall the TV series of that name was about a junk dealer).

Does that wrap it up for you...or--OP--did I get that right?

Item 2.4 described on http://home.online.no/~la8ak/5c.htm
is the solution for dipping pcb coils, and you don't need a
griddipmeter, at all. Another problem with the pcb coil is low
Q-value, and if the coil is loaded too much it won't dip with any
arrangement tried.
also described some GDMs on http://home.online.no/~la8ak/5a.htm -
haven't got the time to re-edit these pages

RE dummy load.
ok found plans for bigger dummy load..but need supplier of non inductive 50r resistor..needs to take full legal load for long as possible..(or 300w continous)intend to use ARRL suppy dummy load design..
UK supplier would be nice but anywhere will do..

thanks g0zen

The RCA 10T tombstone used the new metal tubes, and had an
UltraShortwave band that reached to over 60 mc. Unfortunately,
most of the RCAs had serious problems with the LO dropping off
at about 50 mc orso, very few of the radios ever seemed to actually
tune that high! I think I've seen one example that worked across the
full tuning range without twiddling the circuitry to make it work.
Bu, in 1936, probably no one even noticed, or cared.

the desire for non-inductive resistors is more a theoretical thought,
your problem is capacitance in the sideplates as well as they are
inductive, while all those paralleled carbon type resistors has a
relatively small total inductance

I've shown some note about it on http://home.online.no/~la8ak/m3.htm ,
describing the result using certain carbon resistors which performs
well in a smaller dummy load - even on 23cm

Mounted 6 large 300 ohm 'non inductive' resistors which had been used
as RF terminations in RCA TSL-5 TV transmitters on 210MHz, but it
wasn't much good as 50 ohm dummy-load on 30MHz, just because of
capacitance problem with the mount

Hi,
Dave asked:

>> Would it be possible, though not necessarily practical, to make a reciever
>> for the modern FM broadcast band, using only pre-WWII tube technology?

The Hallicrafters S-37 tunes 130 to 210 MHz and although it dates
from 1945, it uses 954 acorn tubes and could have been made with 1930s
technology. There's a front-panel selector for AM or FM (narrowband
most likely, but the manual doesn't say and I've never tried running
mine).

GDOs are sort of dated by now. i build one last year when i was just getting back into hamming. i found very little use for it over the last 3 months that i have actively been homebrewing. let me explain why ...

a gdo is primarily used to check for resonance of a tuned circuit. if you knew the inductance and the capacitance, you could easily compute the resonanating frequency youself.

as another poster mentioned, getting a dip is a fight. so, what i do use is a combination of three things: an rf probe with a high impedance voltmeter, a test oscillator and a frequency counter. all these things are in themselves pretty useful. but i seldom go wrong in getting properly tuned circuits.

i have a test oscillator (see the schematic http://farhan.net.co.nr/testosc.gif). i plug in a coil with a 330pf capcitance in series between the base of the vfo transistor and the ground. and measure the frequency on the counter. that gives me a pretty accurate (within 1%) measure of the coil's inductance. it involves a bit of calculating, but once i have cast the values, there is seldom need to change them. i tend to do simple maths in my head using 10MHz as starting value for resonance (100pf with 2.5uH). I can now scale up or down without resorting to a calculator.

As for peaking a circuit, it is best done by the ear or using an oscilloscope. peaking by the ear is probably the best, if u can manage it. now, i dont mean to be rude, but frankly very few people have the ear to be able to tune for best fidelity rather than loudness. it takes patience and care (i have very little of either). so, i depend upon a scope. it is a little like knowing morse. it is the best mode of communicating, but not all want to use it.

a poor man's alternative is using the RF probe. the RF probe will never show distortions. But it can show clear peaks while tuning up a circuit. be sure that you also terminate the output of the tuned stage properly! otherwise you maybe be tuning away from the sweet point.

i would rather that you invested into building a simple PIC based counter. It is pretty accurate, you will never need to caliberate it. (I never got around to caliberating mine, it is off by 1.5KHz at 10MHz). That with the test oscillator, you would be completely informed about your coils. An RF probe is a 10 minute project and if you already have a good VOM, you might not need a High impedance voltmeter. I brewed my own voltmeter to keep things completely homebrewed.

the counter can always be used with all your projects as a standard read out. The rf probe will the most useful tool in tuning up any transmitter. The voltmeter is indispensable.

Wideband. I suspect that the S-37 and S-36 differed only in tuning range. The S-36 had an IF bandwidth suitable for FM broadcast. The wouldn't have been any narrow FM in that frequency range in 1945. Certainly no land mobile, and wasn't land mobile about 20-30 kHz wide until post-WW2? Crystal frequency stability didn't get good enough for NBFM at high VHF until the hermetic holders like the HC-6, which are post-WW2, aren't they.

Even HC-6 and snap-action thermostat ovens could be pretty awful. Collins built very special 400 MHz radios for an Air Force project I was on in the early 1950s. Listening to their output frequency with BFO on you heard a kHz or more of drift, with the fractional-minute cycling of the thermostat/oven. Our digital modulation was 180-degree-shift PSK of the 400 MHz carrier, and couldn't stand all that short-term drift. The solution was to disconnect the oven's heater. We could stand slow drift.

| First rule is to get a good dip meter- the stuff made for the amateur
|community is very poor- the Eicos, Heath Millen etc. Pick up a Measurments
|model 59. With this meter you can take a 1/2 wave wire- say at 2M and hold
|the meter a couple inches from the center and see a huge dip. Other meters
|don't even respond when held to the wire. Dips on conventional L-C circuits
|can easily be full scale.

Yep. I have two 59s and they are great. I got rid of two Millens.
They are better than anything else but the 59.

As to usefulness, a short war story. Another engineer and I were
working on an AGC problem in the early Phoenix missile i-f amplifier.
Phoenix being a monopulse radar had a three channel receiver with very
tight agc tracking requirments (both gain and phase). The agc voltage
was fed to each of the three channels via feedthru caps in the walls
of a very well shielded and gasketed chassis. Nevertheless, there was
obvious crosstalk.

The other guy said to me, "Wes, do you have a GDO?"

I said, "Sure."

A couple of younger engineers who were watching this asked, "What's a
GDO?"

So we poke the coil of the Model 59 into the chassis and find a nice resonance at the i-f in the agc wiring. The feedthru capacitance and wiring inductance were resonating at i-f. We had millions of dollars worth of test equipment in our lab and I doubt that we could have devised a test for this without heroic efforts.

The only problem was keeping the GDO hidden from the metrology guys since they couldn't "calibrate" and service them so they wanted them gone.

My S-36 has two selectivity settings, sharp and broad. The broad
position is fine for FM broadcast. I don't know how sharp the sharp
position is.

Farhan, I took your advice about tuning out the subharmonic, although I used a dummy load instead of a 12" wire. I did find a tuning point at which the subharmonic went away. The article says to tune it so that there is a minimum of illumination at the PA indicator lamp, and a maximum of illumination at the RF indicator lamp. I found a point where there is NO illumination at the PA indicator lamp, while the RF lamp glows brightly. Prior to this test, I always tried to have at least some illumination at the PA indicator lamp. Perhaps no illumination is best for this particular incarnation of this rig, given that it still has some problems. I have no scope and no wavemeter (yet) and not a lot of knowledge, so I rely a lot on trial and error, probably too much.

The tuning point described above is also the point where any self-oscillation stops, the subharmonic is silent, and the output is the greatest as measured via a voltmeter across the dummy load, rectified with a diode and capacitor as suggested by KC6WDK. I'm now getting 12 v there.

Now I'll continue to try to find the source of the subharmonic, and also the chirp, which is still a little troublesome. I am also going to try some suggestions made by others who responded.

I realize that I'm rather handicapped, having a 1-watt rig that uses crystals, and having only a "Technician with Morse Code" license. I missed passing the General exam by one question. :(

Thanks to all.

Thanks to Ed for the good advice.

I've got an HP 140T. As far as I know, the only difference between it and the 141T is that the CRT in mine is a conventional one with long-persistence phosphor rather than a storage tube. It uses the same plug-in units as the 141T. I find it to be very usable, and don't really miss storage capability at all. I think the tube is a lot more trouble-free than a storage type unit.

So I recommend that you don't turn down a 140T if you come across one -- and you might even have a better chance of getting a unit with a working display than with a 141T.

Realising that not every ham has a MFJ 259B or similar analyser , this is a really useful instrument and well worth considering ,not only for antenna matching.
The 259B has among its facilities a capacitance and inductance measuring capability.

When mesasuring inductances and capacitances it is very revealing that the measured values do change dramatically at higher frequencies ,especially useful to know when using components in HF and VHF circuits.

BTW I also use an inductance & capacitance meter with LCD readout ,operating with an internal 1000 Hz oscillator , which measures the inductance / capacitance ,obviously at that frequency and is fine for up to the lower HF frequencies.

==========
Suggest you check with Mainline Electroniscs - Leicester.
They probably still have T0220 packaged non-inductive resistors of
25 -50 -100 Ohms.
You might have to use a number to make up a package of 50 Ohms which can
absorb 300 Watts.
These resistors are fine well up to 300 MHz.
You obviously need a substantial heatsink to get rid of the heat.

A US manufacturer of these resistors is Caddock (their UK agent is/was
Rhopoint Ltd -Oxted , Surrey ,tel: 01883-717988)

Their Cooltab TO220 power film resistors ,model MP820 -20 Watts come in a
range of 1 Ohm to 10 kOhms .

Good Luck

Frank GM0CSZ / KN6WH

>THERE MUST HAVE BEEN SOMETHING WRONG WITH YOUR MILLEN. BILL T.

I'm not using a Millen and this post isn't a troll as someone else suggested. The meter I use started out life as a Tradiper (Japanese) but because it was hopelessly outdated and used old germanium trannies with enough lead inductance to tune a VoA transmitter, I decided to rip its guts out and rebuild from scratch.The actual chassis/meter/facia etc was quite high quality, so it made sense. I got this nice circuit from the UK equivalent of the ARRL Handbook and set about building it. It used 2 SK88 FETs and the output of this oscillator could be adjusted to keep its impedence as high as poss for each test, thereby giving really good dips when even quite heavily loaded low Q circuits were tested *provided* they were physically big enough to shove the sense coil into. The sense coils are about 3/4" in diameter, which although fine for large, out-of-circuit component measurements, is *hopeless* for getting in close on a circuit board with subminature components a fraction of the size. That's the main problem I face with all GDMs, though: they all seem to have relatively huge sense coils relative to today's component sizes :-(

==========
The best way to roughly match the 2 impedances is to use any small
transformer which can pass SSTV audio tones.
It is not a critical matching

I don't know the microphone input circuit of the TS430S ,but you can check
that by looking at the microphone itself.
Suppose that impedance is somewhere between 500 and 1000 Ohms and the
audio output of your Laptop 8 Ohms .

It means the impedance ratio is in the order of 800 to 8 is 100 ,so the
winding ratio of the transformer should be in the order of sqrt 100 is in
the order of 10 to 1. So you would have to find any (small)tansformer with
that winding ratio (meaning voltage ratio)

But again the ratio is NOT critical

If the TS430S would have a high impedance microphone in the order of 50
kOhms , assuming a low impedance output from the laptop of say 10 Ohms the
transformer ratio would have to be in the order of sqrt 50000/10 = sqrt
5000 = approx 70.

If you can't find an audio transformer for this application , just try a
small power supply transformer ,since these will pass the low freq audio sig
used for SSTV.

Good luck

i use my GD-meter when building antennas and tuning
antennas and traps to frequency. Although
the calibration is quite inexact, it's always possible
to listen to the GD-meters frequency on the
receiver.

More likely the results of corporate policy. The last place I worked kept the records on the mainframe, rather than use dedicated software to track the ISO9001 data because, "ï¿½That's the way we've always done it!ï¿½".

That is like some test fixtures have elaborate setup and calibration instructions, wile others are labeled, "Calibration not required" I told the cal lab the label should read, "Calibration not possible". ;-)

|Great story, Wes. But why couldn't the metrology guys figure out a cal
|procedure? I suspect the Not Invented Here syndrome, right?

The worst thing that could happen to our equipment was for it to go to
"Calibration." I had more than one piece of equipment "accidentally"
dropped and broken when they tired of maintaining it. If they did
this to an HP/Boonton 250 Rx meter what do you think would happen to a
Model 59?

The best we could do was get an "inactive" sticker put on the
equipment. This took it out of the cal cycle but theoretically meant
that we couldn't use it for anything. Also there were the everpresent
management directives to get rid of inactive equipment to reduce
inventory costs. Imagine how much expense could be written off if
Hughes Aircraft Co (now Raytheon) got rid of a Model 59 GDO <g>.

Might have been enough to reinstate my retiree medical benefit that
was promised to me for 33 years and then taken away. But that's
another story.

This is totally the wrong way to go. Part of the idea is fine but the main problem is cutting down the voltage level from the laptop to a very low level the sound card can use. By going to a stepup transformer you have just raised the voltage by your factor of 10 or 70.

As this type of audio frequency response is not that critical , a simple resistor network of about 100,000 ohms in series with the sound card output and a 1000 ohm reisitor across the input of the mic socket should be in the ball park.

For an inespensive interface, (about the cost of the cables) do a Google search for RASCAL. It is a Rigblaster type interface at almost no cost.

Any of the popular psk31 type audio interfaces should work as they all are just lowering the leverl of the sound card to the mic input.

> Bill, W6WRT
>
That's always been some of its appeal. Throw one together, or buy one,
and you get a tool for finding the rough frequency of a coil. But you
also get that ability to figure out an unknown L or C, you get a signal
generator, you get a wavemeter (which also still has potential use),
you get a general purpose oscillator that you can connect a crystal to,
and you get likely some other uses that don't immediately come to mind.

They date from a time, late forties is when they started becoming popular
but I'm uncertain if the concept was there before, when the average ham
had little test equipment, and even labs and repair places might not
have all that much of it. It was a handy little unit, relatively easy
to build, that did give good returns.

Of course, a lot of recent equipment isn't conducive to as easy use
with a GDO, with self-shielding toroids and the rest shielded in cans.
Construction isn't nearly as wide open as in the days of tubes.

But whether it's worth having likely depends on a mindset. If someone
wants to load down on tons of test equipment, then a GDO is likely
redundant. But a GDO can have its uses, especially if one doesn't have
a wide-range signal generator.

But is it really modern, or just a rehash of what's come before?

I haven't seen the article, but in thirty years of reading the magazines
(and I've seen plenty of back issues from before that), there has been
very little change. Most of the articles are a small variant on a previous
article, with any real change being about coil forms ("I didn't have what
the previous article used", or "I noticed these things that would make a GDO,
so I built one around them") or variable capacitor.

Admittedly, when solid state devices came along, there had to be some change
since people did want to make use of them. The original ones were likely
pretty bad, using bipolar transistors, and of course there was the Tunnel
diode one from Heathkit. Once FETs came along, the GDOs were back to
basically a tube circuit, albeit with low supply voltage.

There have been the occasional outrageous scheme, switchable coils,
or making use of an existing signal generator or building a whole GDO along
such lines, but they never really held. Next time a GDO article was
published, it was back to simplicity.

If I was building one, I'd make sure it had a good reduction drive. I'd
certainly put in a buffer for an output, as a signal generator or to feed
a frequency counter. The latter then means the dial doesn't require much
effort, and the readout will be much much better than any GDO from before.
Maybe I'd even build a plug-in that has switchable coils, but the whole
thing is shielded, for those times when you just wanted a signal generator.

But I'd also be looking at the circuitry of the Millen Solid-state GDO,
from the early seventies. It was a more extensive design, but of course
it costs virtually nothing for those extra active devices. They found they
had to put a variety of chokes in the thing to isolate the oscillator from
the B+ line, so there weren't false dips.

The Heathkit from the eighties seemed rather interesting. Again, it was a more complicated design. I can't remember what the extra circuitry amounted to. That design did generate some similar home made circuits at the time.

I don't think impedance matching is as much of an issue as the level. From what I can tell, Bill had it right. All it takes is a couple of resistors. You got to reduce the level A BUNCH. I don't know if Bill's 100:1 is right, I found the values for my Icom by experimentation, but it's pretty close.

Keep in mind that you want to run the computer's speaker volume pretty high to reduce quantization error. If you adjust the resistance and mike gain so that your power out is somewhat below max when you are generating SSTV, it should be pretty close.

Digipan suggests a 100K in series and a 1K in parallel ... seems like I had to get more extreme, but then I'm connecting up an Icom.

It's not necessary to go back to just a few years after the first
audion. :-)

The Galvin/Motorola SCR-300/BC-1000 used 7-pin glass base
"miniature" tubes, battery type filaments, and was 40 to 48 MHz.
Tube types were 3A4, 1T4, 1R5 in the VHF range. It started into
full production in 1942 and about 50,000 were built. FM. Dan
Noble migrated to Chicago to work for Galvin in 1940...after finishing
a design for the first mobile police radios...pictures show those

tubes to be glass, octal-base. Noble is the chief architect of the SCR-300 walkie-talkie. Interesting little gem of a then-tiny transceiver.

The argument against that might be that 1942 was "after" the entry into WW2. But...those battery-filament (directly heated) tubes were in existance in late 1939. Galvin/Motorola used them in the SCR-536/BC-611, the HF-range "handie-talkie" which was started in design in 1940.

Perusing the MIT "Rad Lab" volumes ("Amplifiers" is the one I have) will show that 6AG5s were already around for radar set IF strips of 30 and 60 MHz. Another 7-pin all-glass "miniature" envelope but with an indirectly-heated cathode. See also the 6AK5. Both are the "short" version (physically short compared to the "All-American Five" types with 7-pin bases and all-glass).

One of the reasons one didn't see those (then) advanced tubes was that the consumer market products still went in for the cheaper octal base kind...sockets were also cheaper, many being made out of melamine-laminate stamp-outs riveted together to hold individual tube pin grabbers (first cousin to solderless joining gadgets). Most of the consumer radio equipment of the pre-1950 era were indeed low-quality "Model T" kind of things.

In pre-WW2 days, a 7-pin all-glass envelope for a tube cost more to produce than the older octal base with pins soldered to tube element leads. All metal envelope tubes cost more than glass envelope types. Once tube makers ramped up for the all-glass 7- and 9-pin little ones, they got cheaper and were used in post-war consumer radios.

EVERYTHING in radio was already in continuous change from the 1930s onward...even if it didn't show up in the consumer marketplace right away.

I suppose it is very interesting for antique boatanchor folks to play with those "stone-age" tubes. Ho hum, I say to self, broke into vacuum tubes using a 201A from an ancient radio. Phooey. :-)
My wife often uses a little AM-FM set with ear-bud listening things, the set about the size of a cosmetic compact case. Was a Give-Away sales promotion thing in the mail. Cost nothing. Obviously no tubes in it. Fine FM, including stereo sound.

Hi,
Thanks for the correction. The S-37 doesn't have any choice of
selectivity, unlike the 36 which had tertiary windings in the IFs.

My Feb. 1942 "FM" magazine has an ad from REL selling FM mobiles for police use. I assume the ad was bought in 1941.

A young engineer who worked for my father at the US Patent Office had one of the MW (AM broadcast) RCA "camera-case" radios about 1940. It was based on the tubes mentioned above. Size was about 2x4x8 inches. Most of the space was taken up by the batteries. The A (filament) batteries lasted about 3 hours.

I estimate the date since this fellow went on active duty with the Navy _before_ Pearl Harbor. In fact, he phoned my father with details of the losses at Pearl the next day (Monday, Dec 8, 1941). Those details were kept VERY secret for at least 2 or 3 years. My father kept the secret, and I think complained to the Navy about the security breach. Apparently nothing happened to the fellow who spilt the beans.

A decade ago I had a struggle with those instruments idiots referring
to ISO 9000, had an old fully working 30 years old Wande&Goltermann
SPM-1 instrument for telex channels, with mark and space marked, but
they would give me a new digital possibly from HP, costing in the
region of $10000 - without the channel marks, but solid state. After a
dispute they agreed to check the calibration, and it was better than
they could measure, so they had to let it pass, but I damaged their
day!

I was told that if any tubes broke down it was forbidden to change
them, and it was a political decision to discard such old instruments

sorry I don't really see your point. I bought my Tradipper in 67, and
it has been very useful since then, I may not use it so often now
because I've also got a Philips GM3121.
Mine operatet satisfactorily - as original - up to 140MHz, but the 2M
coil is no coil at all, only a short between to pins on the connector.
Have described how to improve on this on
http://home.online.no/~la8ak/m2.htm

The other modification is to use external +12V since the battery would
normally be flat when needed, but the original version had "positive-
ground", and some minor changes had to be done

LA3JA later bought the same model, but this had a very bad
intermittent contact in the tuning capacitor, so I couldn't repair it.

DL7QY described a dipmeter covering up to 1GHz, but I haven't really
felt I needed it because it is other ways to check ressonance than
using a GDM, and 1GHz is still not the highest frequency I need to
cover

This double frequency could possibly come from the coupling of two tuned circuits (like in the good old IF). In this case two frequencies are natural. Am I ok ?
I wonder if the coupling between GDO and the measured circuit would be done with a closed loop.

well it is amazing i think how some of these units retain their resale value even though the companies that made them do not service them or back them......man who was the brainiac that thought about how to implement this scam?

incidentally some guy tried to sell a stolen hp unit he lifted over at his job at nasa.......on ebay.....the final price was i think about $3,000.00....for a 35,000 dollar unit i thing they said on the news......he got arrested and the guy who bought it on ebay needless to say didn't get the deal he was trying to get.....which makes me wonder how many stolen items are listed on ebay and are sold there?

Dunno why you guys want to pick on metrology departments.

It's up to CORPORATE to see that metrology departments do
their thing properly. Most of them do. I worked in one for a bit over
two years (Ramo-Wooldrige) and everything was done according to
factory information and procedures. RCA Corporation was done the
same way.

On the other hand, Electro-Optical Systems (a Xerox division) was
terribly lax that way and any department could tag something out of
service and have it stored. EOS Corporate put such loose controls
on it that anyone could go into the storage area and "requisition"
anything, no questions asked.

Designing and building a product to provide many years of use, and then
capable of being repaired without access to unique components and/or exotic
service equipment, is a concept so rare as to be thought a scam.

An excellent book on 'hands-on' RF design is a rather recent ARRL
publication :

'Experimental Methods in RF Design ' by Wes Hayward , W7ZOI / Rick Campbell
, KK7B and Bob Larkin , W7PUA

It covers designs for a large part of the RF spectrum from HF to Microwave.

It is one of the most stimulating publications in this field I have seen for
a long time. It's a real gem !

==========
Apart from (roughly) matching impedances ,a transformer ensures galvanic
separation between PC (laptop) and transceiver , hence avoiding any hassle
due to earth loops .
If the voltage level at the transceiver's microphone input poses a problem ,
a resistive voltage divider can always be added.

Maybe you have a different model. Mine purports to cover up to 360Mhz,
but there is *no way* AFAICS that the thing would be capable of
anything remotely close to that upper range limit, on cursory
inspection of the internals. I'm glad I went for the wholesale
re-build but still find it hopelessly impractical to use on minature,
in-circuit components.

Imagine your cell phone if it was designed to be repaired, and used only
common components. It would be the size of a briefcase. Do you think
cell phones would be popular if they had to be briefcase sized?

What about spectrum analyzers that needed to be contained in several
6 foot high rack cabinets?

Is the world better or worse now that a 100MHz oscilloscope can be made
the size of a paper back book?

I'm trying to find the pinout for an obsolete SEI crystal oven, which contains a HC6U sized crystal socket. SEI are now part of C-MAC, who were unable to provide me with any information.

The oven measures 26 x 23 x 49mm including 4 pins. Presumably 2 pins are for the crystal and the other 2 for the oven heater - but can anyone advise on the necessary supply voltage?

The label reads:

SEI
CRYSTAL OVEN
QC. 1500 A
TEMP. 75 C
SER. No. 077094
MADE IN ENGLAND

Most of the chips in cell phones are off the shelf parts, and there
are places that do repair cell phones. RMS Communications in Ocala,
Florida rebuilds thousands of pagers and cell phones every week. I know
several techs who worked there, and they were telling me about the
equipment they had available at each work station.

One problem with new RF and test equipment is the firmware programmed
into chips isn't readily available to program replacement parts. Another
problem is the short production life for some parts. If you build a
product for over two years, you either do "Lifetime purchases", or
redesign boards to use the next round of parts. What is real fun is a
base product with up to 100 different sets of software, depending on the
customers specifications. Its hard enough to keep it straight on the
factory floor, let alone trying to do it in the field.

|An excellent book on 'hands-on' RF design is a rather recent ARRL
|publication :
|
|'Experimental Methods in RF Design ' by Wes Hayward , W7ZOI / Rick Campbell
|, KK7B and Bob Larkin , W7PUA
|
|It covers designs for a large part of the RF spectrum from HF to Microwave.
|
|It is one of the most stimulating publications in this field I have seen for
|a long time. It's a real gem !

I don't have that one but the predecessor was "Introduction to Radio
Frequency Design" by Haywood.

Glad to be of service. Actually I think the obscure reference was actually
a paraphrased quotation of the service rep, which the OP repeated...probably
should have used quote marks there to clear it up.

It is even worse in the space field, where by the time a part is
qualified, and a satellite is made, the part is stone cold obsolete.

Get a copy of 'RF Circuit Design' by Chris Bowick (Newnes). It's a
mine of useful info on designing your own stuff; recievers and
transmitters. A remarkable reference work and not too expensive,
either!

And then there was the sub-harmonig generator with zero plate volts,
power going in to the plate and power out of the grid.
Not a joke; saw it done at Sylvania in the late 60s.
Used a tetrode, 2nd grid had about 30V on it to act as a plate in
Hartley oscillator configuration.
Set to not oscillate with zero signal, would "slowly" ring up on
application of RF; like someone sitting on a swing and then starting it
by mere pumping.

I don't know why you're having so many problems. I've aligned many the VHF Engineering and Hamtronics VHF (and UHF) Transmitters through the years using the volt meter alignment information.

I was at Kinkos (my office anywhere) making copies of the VHF Engineering 2 meter tx strip yesterday. If you are actually serious about building this type of transmitter, drop me a note through the http://sonic.ucdavis.edu web server Email icons and I'll send you copies or scans of the paperwork.

chow for now

Hello Group!

This summer I saw someone selling really nice small frequency counters for microwave (up to 10 or 18GHz) in the flea-market hall at the HAM-RADIO fair. He also had prescaler modules with SMA-connectors and loose prescaler chips.

All of these were out of budget then so I just noted in memory they existed. Now there is a need.

Does anyone know who I'm talking about? I have done some searching on the 'net but I find nothing that looks as good as this guys boxes and modules.

3601. Perfect data decoder for SWL?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-17 21:52:52 UTC
From: Sholto Fisher <nospam@nospam.com>
Message-ID: <Uqbub.4937$n56.2405@newsread1.news.pas.earthlink.net>
Source record: 30917

Hello all,

This might seem a strange request but I am in the process of building a data-decoder for reception of various modes (started as a project for myself) and am now thinking of making it available as a low cost kit for sale. I would like some input from SWL's as to what they would like to see in a 'perfect data decoder'

Some of the features it currently has are:-

1) uP 'smart design' (ie, decoding is done in the unit and output is done via RS232 to PC, this should make it able to run on any system with a terminal emulator program)
2) Selectable band-pass filters on the input to improve s/n
3) Die-cast case/RS232 connector & shielded cables to minimize PC noise.
4) LED tuning bar-graph
5) Switchable (unfiltered/filtered) head-phone out jack with separate volume control.
6) Modes currently supported: CW, RTTY(45,50,75,100,110), TOR, FEC - any other modes you would like to see? doesn't necessarily have to be HF specific modes.
7) Upgradable 'firmware' via RS232.

Any ideas anyone?

Do you think anyone might buy something like this?

Answers on a postcard please.....

sholto AT mfire DOT com

hmm, kind of like buying a computer ...in a few mounths it is
obsolete...on the tektroix and hp stuff.......you would think that
they would be feeling the heat from asia like everyone else.....just
how much profit is there in a unit that sells new for $75,000.00? and
why may i ask after 10 to 15 years it still sells for heavy cash....

I have had success as well using an RF probe and voltmeter. Tuning for peak and once you start into the multiplier stages, the wattmeter should start to get a tickle and then climb as you go through them as well into the final stages. When you get this far, a freq counter near by should show some freq. Then go back and touch it up if need be. G.W.

3606. Electrolytic coupling capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-17 22:49:46 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0311171449.7693ad86@posting.google.com>
Source record: 30923

As you know, coupling capacitors are used to minimize ripple in batteries/power supplies. This is important, because even the slightest ripple can cause an IC to behave incorrectly.

I understand the role of ceramic capacitors. Ceramic capacitors are used to couple RF ripple and thus minimize RF interference. .1uF seems to be a popular value. At 1.8MHz, the capacitive reactance of a .1uF capacitor is .884 ohms, and the ESR is usually a small fraction of an ohm and not significant.

I have also seen circuits that use smaller value capacitors. What's the point of .01uF and .001uF coupling capacitors? Is the stray inductance THAT much lower? I have 1uF 50V monolithic ceramic capacitors (JIM-PAK MD1), and they're actually smaller than my .1uF 50V ceramic disc capacitors (DC.1). Why doesn't everyone just use 1uF ceramic capacitors for power supply coupling? At 1.8MHz, capacitive reactance of a 1uF capacitor is only .0884 ohms.

What's the point of relatively low value electrolytic capacitors? Their ESR values are usually on the order of 10-100 ohms. At 60Hz, a 1uF capacitor has 2650 ohms of capacitive reactance. A 10uF capacitor has a capacitive reactance of 265 ohms, and a 100uF capacitor has a capacitive reactance of 26.5 ohms. Given this, shouldn't all electrolytic capacitors be at least 100uF? Is there any point to a 1uF electrolytic capacitor when there are 1uF ceramic capacitors that have the advantages of lower ESR and nonpolarity? (Connecting an electrolytic capacitor the wrong way will cause its internal material to boil out and make a big mess. Connecting a tantalum capacitor the wrong way will start a fire!)

>As you know, coupling capacitors are used to minimize ripple in
>batteries/power supplies.

"Coupling" is usually used as a term for capacitors which are actually in the signal path - they're used to pass signal and block DC.

Power supply caps are usually referred to as "filter" or "bypass" caps.

>electrolytic capacitors be at least 100uF?

Not necessarily. There are several other issues to take a look at.

For one thing - examine the _actual_ ESR/impedance of electrolytic caps over a wide frequency range. You will observe that these caps tend to behave in a capacitive fashion only up to a certain (self-resonant) frequency... above that point, they behave much more like inductors. This is due to the inductive reactance of the spiral-wound foils (or metallizations on the plastic films).

The higher the capacitance, the more "turns" the foil/film takes inside the can, and the higher the inductive reactance. This can lead to the larger caps having a lower self-resonant frequency, and a reduction in circuit stability at high frequencies.

> Is there any point to a
>1uF electrolytic capacitor when there are 1uF ceramic capacitors that
>have the advantages of lower ESR and nonpolarity?

Yup.

Circuit stability can actually suffer if you try to do all of your power supply bypassing using low-ESR, high-Q capacitors. These capacitors can interact with the inductance of the wiring (or PC-board traces) to create high-Q resonant circuits. If your circuit's

operating behavior tends to excite one of these resonances, you can get some very severe "ringing" on the power supply lines.

An easy, and common way to prevent this from being a problem is to "swamp" the high-Q resonances, by including substantial amounts of lower-Q (higher-ESR) "bulk" capacitance on the power supply rails. A rule of thumb I've read is to include about 10 uF of aluminum electrolytic, or 1-2 uF of tantalum, for every half-dozen TTL ICs or op amps, and to have at least one such "bulk" cap every 4" or so on the board.

The interactions between wire and trace inductance, component lead inductance, capacitance, ESR, etc. are many and subtle.

> why may i ask after 10 to 15 years it still sells for heavy cash....

When you look at the price of a $75,000 unit, consider this: First, the test equipment market is really rather small, nothing like the consumer electronics market, and second, bleeding edge technology test equipment requires some serious money to develop. Tektronix and HP have historically been positioned right in the front of the technology wave. So, a unit that sells for $75,000 may have cost $20 million to develop to where it could be manufactured. It probably only has a market life of 1000 units. Then the actual manufacture of the product costs something. A good round figure is the ratio of parts cost to sale price is 3x to 4x. Labor figures in at about equal to parts cost.

-20,000,000 to develop
-25,000 x 1000 units = -25,000,000 parts cost
-25,000 x 1000 units = -25,000,000 labor cost
75,000 x 1000 units = +75,000,000 sales price of instrument

Bottom line +$5,000,000

Take that $5 million, and subtract some for advertising, and service, and you haven't got much left.

Granted these numbers are just guesses, but I have been doing small quantity manufacture for a lot of years, and these kinds of ratios come up again and again.

As to why the Tektronix and HP stuff commands a high price in the used market, the reason is simple, the gear is high quality, has very high capabilities, and the price of a new replacement is also high.

have u actually tried connecting the output of your speaker directly
into the mic input? i bet you a 2n3904 that it would work. you can cut
down the audio output using the volume control applet.

even if you do horribly overdrive the transceiver, you dont have to
sweat because the SSB filter will clean out any out-of-passband
distortion. and sstv does not use any amplitude variations (i am not
aware of the newer SSTV modes) so clipped audio will not be very
different to the remote receiver.

as usual, i guess, you should simply plug in the sound card output
into your mic input to see what happens.

i have used my homebrew on PSK31 without any attenuation. it works
pretty well. infact, i got into PSK31 by hanging my PC's mic over the
speaker box and tuning the sigs using WinPSK. On a dare, I left my
transceiver mic on top of the PC's cambridge work speakers and started
working PSK31 dx right off. the next night i searched around for a
pair of cables and connected the rig and the PC together without any
other components.

i have used RTTY, SSTV as well as PSK31 without any electronics in
addition to ordinary cables.

Believe what you want, but the place has around 100 employees, and
was looking at buying the old L3-Com/Microdyne complex to expand into
its 120,000+ square feet of buildings and acres of land for parking.

They are bigger than Microdyne was when it closed the complex and
moved to Pennsylvania. If there is no money in repairing pager and cell
phones, why do they want to buy property which is priced at 1.6 million
dollars? Here is the listing for the complex:

Source record: 30932

Hi

for my quite unstable counters I've got some 0.1ppm 9.6MHz VCXO's (guaranteed over temperature range -20...+20°C), the problem is that the original XO is 1MHz with 7490 divider, and now I need a divide by 96 downcounter. The VCXO drives a 74LS14, so it shouldn't be any fan out problem, but I am not aware what is the readily available divider to choose. The counter is mentioned on http://home.online.no/~la8ak/m21.htm , but it is Norwegian text

Getting proper, fine control of the volume level might be very
difficult with this approach.

>even if you do horribly overdrive the transceiver, you dont have to
>sweat because the SSB filter will clean out any out-of-passband
>distortion. and sstv does not use any amplitude variations (i am not
>aware of the newer SSTV modes) so clipped audio will not be very

Hmmm. How about intermodulation issues? That might cause a fair big
of gunk even within the audio passband.

>as usual, i guess, you should simply plug in the sound card output
>into your mic input to see what happens.
>
>i have used my homebrew on PSK31 without any attenuation. it works
>pretty well.

How the the signal actually look (and measure) on the far end? How
were the IMD levels, and how far did the PSK31 signal's sidebands
extend?

Even if it "works pretty well", I'd be concerned about shoving audio
distortion products out well away from the signal. This might not be
too much of an issue for SSTV, which is using voice-grade bandwidth,
but I _really_ wouldn't want to do it when working PSK31. One of
PSK31's benefits is its extremely narrow spectrum width, when tuned
properly.

I've seen some really beautiful (narrow and clean) PSK31 signals on
the band. I've also seen 'em with sidebands blasting out in both
directions, across the full width of the spectrum/waterfall display,
as a result of people overdriving their audio inputs or forgetting to
turn off their compressor/processor or driving their RF finals up to
get the last little bit of power out of their TX. When this happens,
the narrow-bandwidth spectum-sharing benefit of PSK31 go right out the

window, and the signal can become harder to copy reliably.

As to the original poster's question: there are a number of commercial products designed for PC/rig interfacing, and numerous homebrew circuits as well. The simplest designs simply include a resistive attenuator (a fixed resistor pair, or an audio-taper potentiometer) to drop the speaker output level down to mic levels. More complex designs often include transformer isolation in both the TX and RX audio paths, to break ground loops and keep RF out of the audio path.

Any interface designed for PSK31 would probably work very well for SSTV as well. See http://www.qsl.net/wm2u/psk31.html for schematics of both resistive and transformer-isolated versions.

On the commercial side, the best-known are probably the RigBlaster (http://www.westmountainradio.com/) and the Rascal / GLX (http://www.buxcomm.com).

I've used a Rascal (pre-GLX version) quite successfully, to operate both PSK31 and VHF packet from my Dell laptop.

Search through Goggle groups in sci.electronics.design for a divide
by 3 counter, and follow it with five stages of divide by 2 counters.

96/3 = 32
32/2 = 16
16/2 = 8
8/2 = 4
4/2 = 2
2/2 = 1

You want the odd counter somewhere before the final stage to maintain a
50% duty cycle.

Source record: 30936

i guess, i didn't explain the nature of the problem clearly. i CAN tune my current transmitter easily. I just don't think that many will be able to do so as i am building this as a club project.

The reason is that .. it is easy to mistune your transmitter to another harmonic. this is especially true of VHF where the preset capacitors can swing a wide frequency range within their 22pf range.

i was thinking that, instead, it might be a better idea to depend upon generating the signal directly at 144MHz.

that said, as of now, i am continuing to use the a crystal at 18MHz fundamental and multiplying it through three balanced doublers to 144MHz. In my second version, i have replaced variable capacitors in the doubler outputs with fixed capacitors and tunable inductors. that way, i hope to be able to restrict the tuning range of each doubler output centered around the required second harmonic. it is tough work, but that is what differentiates homebrewing for yourself from homebrewing for a group project.

I'm not trying to be difficult Michael. The reason I have trouble seeing how this is a money making venture is the low price of cell phones and pagers. When a Cell phone lists for $99, how much time can a technician really spend fixing it?

In the repair business, the maximum repair price you can charge a customer has to be less than 40% of the cost of new, or they will always walk away. If they walk away, and give you their phones for free, then perhaps you could make a little bit fixing it and selling it, but really, now, tracphone sells refurbished nokia 5185i's for $39. There is not much margine in that.

Who pays for the time necessary for the technician to open the phone, diagnose the problem, unsolder the offending module, test the phone, reassemble, and pack? You would have to pay your technicians less than $10 per hour!

They may have been similar to the Hittite Microwave prescalers and
evaluation boards.

Goto http://www.hittite.com and select "Dividers & Detectors".

Click the "Order" button next to the prescaler you need. You can then
choose to purchase complete evaluation boards (with SMA connectors).

Some reverse engineering, perhaps? Do the crystal socket pins connect directly to a pair of external pins? Is the oven control electronic or mechanical? If mechanical, find a voltage that has the oven on about 50% of the time or a bit less and you'll probably be very close to optimum. If electronic, be sure to get the polarity right, and run the voltage up slowly to see where the oven goes into control. I'd guess that about 50% more voltage than that (about twice that power available) would be reasonable. There might be a tantalum bypass cap on the power that would give you a clue: I'd expect max input V no more than 70% of the cap's rating. Or maybe you'll get lucky and someone will have actual specs for you.

Cheers,
Tom

The 74HC4059 (or 74HCT4059) should do the trick. It may be a bit hard to find, but will divide by any number from 3 to 16384. It is logically the same as the RCA CD4059, but I don't think the old RCA part will work at your frequency. I can't find my data book right now.

Oops, I may be wrong about the maximum division ratio of the 4059, but it is certainly as large as 4 decimal digits (not binary). Again, I can't find my data book right now.

Isn't the 74(LS)92 divide by 12 counter available anymore ? With an addition of a 74(LS)93 divide by 16 counter (divide by 192 total), you can get the required divide by 96 ratio, if you skip the independent divide by 2 section from either the '92 or '93.

If you can not get the '92, get two '93 chips, let the first divide by 16 down to 600 kHz. Using only the divide by 8 part of the second '93, detect the "6" count with a two input AND/NAND gate and reset the counter. IIRC, the '93 contains a built in two input NAND gate in the reset circuit, so these inputs needs only be connected to the two most significant outputs of the divide by 8 counter. The required 100 kHz output can be taken from the most significant output (it has a 66:33 output ratio). If you need 50:50 ratio, first divide by 8 in the first '93, then by 6 in the second '93 and then by two in the independent section in the first '93.

It is run like a factory, not one up repairs. That makes a huge
difference. The techs don't disassemble the units. the production people
do a quick test, clean up the cases, and send the boards to be repaired.
A lot of repairs are new crystals, or reprogramming the synthesizer, or
replacing a bad LCD display which is done before a tech sees it.

Also, they do large runs of the same unit, then do a different model.
Also, some only need a few pieces of the case replaced, and the password
cracked so it can be reprogrammed in the field.

They have service contracts where someone ships a 1000 pagers or 100
cell phones and they repair what they can in a fixed time. They either
return the bad units, or replace them with their own stock of repaired
units, depending on the contract. they also repair a lot of older models
and sell them overseas.

Thanks but... further investigation revealed that neither of the crystal socket pins connect directly to any of the 4 external pins. Presumably this implies the oven contains integral oscillator. The oven control is electronic, and none of the circuit is accessible. The box is soldered (perhaps welded) together except for a lid in the opposite end to the 4 pins, and all that is visible inside the lid is the HC6U socket and a multi-turn preset temperature adjustment potentiometer. Not looking too hopeful as yet...

We were talking about repair and service equipment, not consumer items. A
consumer item is expected to have a short life-cycle, and repairability is
often not a concern.

I never saw "multi-six-foot-rack analyzers"; the oldest & biggest I can
recall were Singer FIM analyzers, which were about 24" wide by 30" tall and
deep, and took four guys to move them (and the plug-in RF heads were a
one-man lift!). OTOH, everything inside was reachable and easily repairable.

If that 100 MHz scope can be built to have a reasonable cost to lifetime
ratio, then it could be considered a consumer item, and a non-repairable
investment. But to me, if I have to pay $10k or more for a piece of test
equipment, it had better last quite a few years and allow me to do
re-calibration and even moderately severe repair.

A very good analyzer series, but generally still priced out of the hobbyist market. Reasonably portable, and ruggedly built. Performance is generally a bit lower than the 856x series, but still very respectable. Much more useful than a hobbyist-affordable 141 analyzer, and easier and more versatile than an older 8569 analyzer. Unless your needs are exotic, the 859x series will be a good industrial choice.

For the spectrum analyzer part, the best a hobbyist can usually afford is an HP-141, with a few plug-ins (IIRC, they offered a total of 6, collect the whole set!). And you will need the HP manuals (some of which are available free from the US Army LOGSA site). And you will need some other basic and decent lab gear (scope, counter, DMM, sig gens) to do the job right.

Sorry, but I can't comment on any Network Analyzers.

Don't forget "ground bounce." That is one reason why each IC had a 0.1 uF capacitor adjacent to it. The signal going into the IC might look clean, but if a large number of outputs switched simultaneously, the ground level in the IC would change and if a signal was at a threshold level, it might pass through it twice, giving a false extra pulse.

What devices would have all of the outputs go high or low at the same time? A ripple counter at one time or another would have all outputs go either high or low at the same time.

Al

If you cannot see the relationship, then you need to stretch a bit.

Everything in electronics, test equipment especially has grown in complexity and performance, as it has been reduced in size. Some of the reductions are there to make it possible to fit more test equipment in a given space, and some are there because of necessities of the new technology (eg. microwave speeds and low power consumption are better done with tiny sized components.)

>
> I never saw "multi-six-foot-rack analyzers"; the oldest & biggest I can

Was your life, as a technician that is, made better or worse when that same 4 man lift SA was reduced to one that you could carry yourself with one hand, while carrying your 1G scope with the other?

How about performance? Did it help you to have the bandwidth limit of your old 4 man lift SA rise from 1GHz to 300GHz? How about your 30MHz scope that is now 1GHz? Did you notice that the prices went DOWN?

How about the heat generation? Have you ever worked in a lab that had no effective air conditioning, and also had a herd of Tek 500 series scopes whirring away?.. in the middle of the summer? I have, and I am quite happy not to do it anymore. We saw temperatures as high as 120F at times. No windows, one door, lots of fans. Turn off the equipment, and the AC did quite fine.

And finally, how about the space savings? Does it help you or hurt you to recapture that floor space the old SA, and scope, and signal generator used?

Tiny little custom component ridden hard to service test equipment made it possible to move away from that kind of scene.

All of the $10K+ stuff I have seen from HP or Tek would easily meet your needs. Calibration? You cannot be serious. Most of this stuff is so finely calibrated that it would be beyond the capabilities of anything but an expert calibration lab to accomplish the task. Just having the standards necessary takes a whole lab... and a whole budget. I know this because I tried to set up a NIST traceable cal lab for my business, and eventually concluded that for me to do that, cal would have to become my exclusive business. I still have all the standards and equipment, but no time to put them to use... No money to keep them in cert with NIST. It is FAR cheaper to send the stuff out and get it calibrated.

The "consumer grade" goodies in the test equipment market don't really need more than a simple calibration checking. I cannot tell you the last time my little Fluke DVM needed recalibration... Because it is 15 years old, and it has NEVER needed recalibration. Has something to do with the little fidgety custom components that are inside it. Same goes for my Tek 2465 scope.

>section in the first '93.

An alternate is to use a chain of presettable binary or decade
counters such as the 74HC160 or 74HC190 families. Or use
74F series to assure high speed...

Since you have a need to divide by 96, a 7-stage binary chain
that would normally divide by 128 can be preset to a state of 32
at the end of the count. The count chain then goes through 96
states before reaching the end of the count again...which can
initiate the preset. [all the other stages not preset would be
tied to ground] The 8th stage would simply be unused

Initiating the preset pulse can be a simple C-R coupling to get
about a 40 nanoSecond spike at the end of the count. If you
think you need it, you can use a spare inverter or a single bipolar
to couple the end-of-count transition spike into the Load pins.

With the 190 family you get a choice of Up or Down counting to ease your arithmetic...which can be adapted to the division control lines if there are a lot of different states selected.

I'd recommend synchronous counter ICs running at 9.6 MHz.

With the 190 series the input loading is only two gate inputs for parallel synchronism using two binary ICs. Same with the Parallel Load line. Internal chip buffering handles those. Only two 16-pin DIPs needed to do the job. Some of the older datasheets have example circuitry for preset counting. The 160 and 190 families have been around for a few decades, are still used in new designs and still available.

well some guy who has a company that i guess is in the business of
buying refurbing and selling electronic equipment has one on ebay for
about $2100.00. should i cross my fingers and go for it? he takes
credit cards. he says it is working very well, it looks real good
according the pics he has of it and it has a fresh calibration.

QRPp International Radio Club sells crystals for the popular QRP channels via the net. I ordered a crystal and paid for it via PayPal over two weeks ago.

This group sells but this is not to be confused with shipping or answering email.

Should I just chalk the $7.00 up to a bad experience?

IF they have to have them made, ie they are out of stock.... it can take 2-4 weeks to get them made. Anything less than that is considered by Crystal Manufacturing companies as "RUSH" and they charge out the ass for it. What you may get for $10 with a 4 week delivery could cost $50 for faster service - not to include shipping. They MAY just be out of stock. Did they say anything in fine print about delays, etc???? READ the fine print. Otherwise, they should send notice if they have a problem. I think Pay Pal has some sort of program included to prevent rip offs, perhaps e-mail them. IF you used a credit card, notify them as well. G.W.

Ask for our list of items on clearance!

I really should have remembered the 74HC40103 presetable divider - I designed one into a circuit just a few years ago..... There is a fairly similar 40102.

My suggestion of the 74HC4059 was overkill by a hard-to-get part.

Thanks for the suggestion, I've used CMOS for almost 30 years and only
use TTL when it is no other solution, one such device is with the 7493
as OH3LWR mention (believe it could divided by some strange factor,
too). problem is that I have hundreds of standard CMOS devices and
they usually (except Philips devices) goes near 10MHz. The reason for
choosing a down counter is to avoid asymmetrical output signal which
might upset the counter if the oscillatorboard has some distance from
the old dividers, but is still some 7490's left in the chain.

You can make a ÷3 out of a couple of J-K flip-flops, then use that to clock a 5 stage binary counter. That way you get 50% duty cycle square waves at 1.6 MHz, 800 kHz, etc. all the way down.

```
Just a suggestion -- there are many other ways.

Dr. G.

Laura,
Judging from your Lat/Long, you're in BC right? So maybe you can help me.

I made an attempt to find EMRFD in Calgary and came up with this:
1) web page of Chapters.ca - no such ISBN
2) phone call to McNally Robinson bookstore - can't find it in their computer

So, did you buy your copy in Canada? If so where?

Any fellow canucks,
What is the best place in CA to order EMRFD?

Thanks,
Gavin

Unless some of the big ham stores carry it, I suspect it's not off the shelf
anywhere in Canada. The audience is too limited, and I don't see it (yet)
making inroads to non-hams. Something like the ARRL Handbook shows up
in bookstores, but it's been around for decades and is often offered
as a good intro to electronics and/or construction, even to those not
interested in amateur radio.

Check the Radio Amateurs of Canada website at http://www.rac.ca They
have a list of places that sell their books, and those ham stores are
the places I might expect the book. But even then, as the technical side
of amateur radio fades, they may not bother stocking the technical books.

I bought an ARRL Handbook a couple of years ago from Radio HF here in
the Montreal area, but it turned out they didn't have it in stock, and I
had to wait while he collected enough orders to make an order to the ARRL
worthwhile. http://www3.sympatico.ca/radiohf When I ordered, he
was offering free shipping in order to entice those orders, so the
delay wasn't bothersome. But I haven't bothered asking him if he
has any in stock, and I'm not sure if there is any great reason
for ordering in Canada if you have to wait for a shipment from
the US first.

So, it might be simplest to order from the ARRL, http://www.arrl.org
I guess when I finally get around to it, I'll do it that way.

you are quite right. about the intermod levels. i just ran a check on
my PC sound card and this is what i have to report:

1) audio output from the PC sound card is 1V v p-p. The mic input
required is 10mV (unless there is a built-in preamp in the mic, this
is common to some japanese rigs). Thus, u need a 1:100 attentuator. A
10K and a 100 ohms resistor in series would do the trick. I suggest
100 ohms so that the impedance into the mic remains low and noise
free. further, i would also suggest that u place a 1000pf across the
mic input close to the mic jack.

2) audio input required into the PC sound card is 10mV. This is as per
the PC sound specs in the web. If we assume about 50mW audio from the
transceiver across an 8 ohms load, we are looking at V = sqrt(0.050 *
8 * 2) ~ 500mV. I think that a similar attenuator will suffice at this
end too.

Hello all,

I would like to build the best all around omni-directional antenna,
that would have a good gain, in the FM broadcast band.

Any thoughts would be commended.

Sincerely,

Patrick Cambre

I can't assess risk for you, but $2k sounds like a fair price for a good
condition 8590.

You keep mixing the needs of an enterprise with those of a hobbyist. True, many of the people on the groups of this thread are electronics professionals who also have an electronics hobby interest. My comments have all been aimed toward the hobbyist. If you have a 2465B scope (one of the finest analog scopes I have ever used), then you are one extremely wealthy hobbyist, and the economic constraints most everyone else lives by must not apply to you.

A hobbyist doesn't send anything "out" for calibration; they rely on the ability to cross-check their various gear with everything else in their collection. Sometimes, they might be able to compare one of their items with a professionally calibrated and traceable item. Or maybe they buy a new DMM, that's rated for 0.1% (whatever) and then proceed to adjust the rest of their stuff into agreement with that one new item.

My point is that old equipment is repairable. Your point is that newer equipment is chock full of value, more reliable, and is easier to lift. There's no contradiction between these positions.

BTW, your DVM always "needs" calibration, even if it is still within tolerance every time it's checked. Nice to know that it's stable, but nothing lives forever. As for "fidgety little components", should you ever apply a few watts of RF to the input of your 2465, you'll find it very difficult to repair by yourself, and the Tek bill for the job could very well approach the replacement cost. If the same had happened to a 465, then you would just be replacing a few small, precision resistors.

This might be a bit off the exact topic but I have a friend who has a HP
141 and the horozontal display scan has shrunk and folded over on top of
itself. Having never worked on test equipment, I could only offer
generic possibilities, (Voltages, deflection transistors, caps?). Is
there are common part failure that can cause this to the best of your
knowlege?

Thanks,
Dave

3659. FA: ATV Video Overlay w/ PC keyboard interface

The PIC STV5730A on screen display project board provides a simple platform for text over video applications. It is ideal for creating on screen displays for ATV applications such as callsign generation.

The unit offered for auction is a demo unit. There is some minor cosmetic damage to the enclosure.

Hi Ed,

What I am NOT doing is trying to mix the needs of the hobbiest with the realities of companies that build for professionals. You are lamenting the fact that the newer gear is hard for hobbiests to maintain. That argument will go soft on HP or Tektronix, or any of several dozen other equipment manufacturers that make equipment for professionals.

The simple fact that your abilities at repair stop at thru hole, technology, doesn't mean that devices that use hybrids, and surface mount technology are not repairable. The hybrid front end on the 2465 is quite repairable, but requires a little optical help, just like watch repair, an 1800's tecnology. From what I have heard, most of the parts in the hybrid are standard off the shelf surface mount faire... I have no direct knowledge of whether this is actually true. I did find it to be the case with the output hybrid in HP's 86222A sweeper plugin.

There would be no more point in taking your busted 2465 to Tek for repair than there would be for your 465, they won't work on either.

Checked is not the same as calibration. The case doesn't even get opened for "checked".

And to your assertion that I am a rich hobbiest, I am not an electronics hobbiest at all! I am a self-employed electrical engineer, and I use the test equipment I own to earn a living. Sadly, for me electronics died as a hobby when I started getting paid to do it. The happy part is I truly enjoy my work!

-Chuck, WA3UQV

(I will admit that VERY obsolete electronics retains a hobby sort of thrill for me... Old tube gear, and old minicomputers.)

There are very few omni-directional antennas that also have gain. Are you using this for a transmitter or a receiver? If for a receiver, you also need some bandwidth, unless you want to concentrate on a small segment of the 10mHz band. For a part 15 transmitter, bear in mind there are some restrictions on antenna size.

I've gone through the same excercise on the 2m Amateur Radio band, in an effort to have as wide a coverage as possible without resorting to a directional beam.

My solution, which might also work for you, was a colinear array of three sections. You can find design information on the web or in the ARRL Antenna Handbook. For 100mHz, a 3 element colinear would be about 8 feet high. You could also use a J-Pole with colinear section which would only be about 6 feet high. The colinear requires a matching coaxial balun at the feedpoint, the J-Pole has a built-in matching stub and may be fed directly with 50-ohm coax. The disadvantage of these antennas is that they are fairly narrow band. You just can't get something for nothing these days. :-)

If you can't find colinear or J-pole information on the web, but this sort of antenna looks interesting to you, drop me a line and I will direct you to specific sources of information.

Thanks for the advice.

I had assumed that if Chapters didn't have it then Amazon wouldn't either,
but I was wrong on that. Turns out it was available from Amazon.ca, so
that's where I placed the order.

Newington, Connecticut. :-)

I bought my copy of EMRFD directly from the ARRL.
Amazon.com have it too. I'd love to spend more
money at Chapters, but they seem to be more interested
in candles and such nowadays.

Books are duty free in to Canada (always have been),
and if you catch Canada Customs on a good day they
won't hit you for taxes either.

>I would like to build the best all around omni-directional antenna,
>that would have a good gain, in the FM broadcast band.

The following is a little long....

I've never made any bandwith measurements, but I've made and used several copper-pipe vertical collinear 2-meter antennas which have served satis-factorily (i.e., they have withstood ice-storms, I "get out", etc.) for many years. I don't recall where I got the original design, and, having just stepped outside and measured one, I'm surprized at how much my vertical element length differs from that described on page 156 of my old (1972) "Radio Amateur's VHF Manual", but I heartily recommend them for their ease of construction, ease of mounting, and ease of matching:

X Y Z (see sketches below)
VHF Manual # 1: 0.475L 0.25L small
2: 0.64L 0.11L small ("small" is never defined!)
where L (Lambda) = wavelength

Note that the total lengths of both designs is the same: about three half-wavelengths. The second design is an "extended double-Zepp" and supposedly gives slightly increased gained and lowered radiation angle.

The VHF manual suggests using balanced transmission line or coax and a balun, but I just use coax tapped on the horizontal part at the minimum-SWR point found by trial and error. (Mentally, I think of the impedance at the shorted end of the horizontal section as being zero ohms and the impedance at the open end being in the neighborhood of 4000 ohms and I start tapping at an appropriate distance between for 50-ohm coax!)

Assuming 146 Mhz and calculating L = 11200/Freq (MHz) = 76.7 inches
X Y Z
VHF Manual # 1: 36.4" 19.2 small
2: 49.1 8.4 small
Mine: 42.5" 19.5" 2.5"
where L (Lambda) = wavelength

I've made at least four of these things; basically, ONE 10-foot length of half-inch copper and four matching elbows should come out just right (allowing about a half-inch each direction for each joint, this takes 2x19+2x41=120 inches of pipe). But when I couldn't get the SWR down as far as I felt it should go (about 1.5:1), I extended both vertical sections with a few more inches of pipe.

My first modification substituted two T's for the two elbows at the open end and added a three-foot wooden dowel (with a just-fit diameter) extending about a foot and a half into each vertical section and crossing

the "open" end for additional support.

I mounted my first one (#1 below) by (essentially) drilling a couple of holes through the short vertical pipe and nailing it to the wall! One could also lay U-shaped bracket(s) across the shorted end and screw them to the wall or clamp them to a tower. But some other designs (two of which use FOUR T's and NO elbows, and the third uses FIVE T's) give better mounting possibilities:

With design #2, the two horizontal copper-pipe stubs may either be inserted into holes drilled in a board and pinned by driving nails through the edges of the board into the stubs, or the holes may be drilled slightly UNDERsize in a pole and the stubs just driven into the holes.

Design #3 just gives more room for nails or clamps.

There is a little problem with wind trying to swing the antennas around the shorted end like a gate on a hinge, so design #4 adds a FIFTH T CROSSWISE to the plane of the rest of the copper and eliminates all swinging tendencies!

As Doug mentioned, it's not so easy to get 20% (20MHz centered at 98MHz) bandwidth and gain and "omnidirectionality". Of course, it can't be truely omni and have gain: best you can hope for is omni in the horizontal plane.

That said, the next issue is "best all around". What exactly do you mean by that? How much gain is "good"?

If I were doing it and needed it to cover the whole 20MHz, I'd stack however many full-wave vertical doublets I could manage and feed them with a harness to keep the feeds in-phase. I'd separate them vertically by enough to keep the mutual coupling moderately low and perhaps experiment with that (or model it) to optimize the phase of the mutual coupling. I'd probably make the doublets with fairly large diameter tubing, or use a "bowtie" arrangement, to keep bandwidth high.

If I was concerned with only one frequency, or a narrow band, I'd use a coaxial collinear because it's relatively easy to build and mount and feed and get working properly (IF you understand how it works). That's assuming I wanted to use at least four elements; fewer than that and it's probably not worth the effort.

But also beware that the vertical collinears will give you vertical polarization and that may not be what you want!

Cheers,
Tom

>Any thoughts would be commended.

FM broadcast is usually horizontally polarized. You can borrow from
the small general aviation "rudder" antenna for the VHF 108-137 MHz
civil aviation band.

That one is two half-wave whips at right angles in the horizontal
plane on the plane's vertical stabilizer. Feed it like a half-wave
dipole. Impedance will be somewhere near 75 Ohms; in aircraft
installations that depends on the vertical stabilizer structure.
Has a fairly good omnidirectional pattern.

It's easy to scale up slightly in size to the FM band. Transmission
levels beyond Part 15 regulations is illegal.

So Chuck your looking for a Trash 8/E rather than a Trash 80. BTW my
Trash 80 was a real Trash 80. R.S said it was uneconomical to repair,
read out of warrenty replaced a bad ttl chip and away it went. A friend
reworked the firmware to get rid of the infamous keyboard and cassette
problems(we rescued 8 of them from that dumpster).

Snort! That's a good one! I spent too much time using the original
TRS-80 to ever really want one. In one of my first consulting jobs
I wrote a bunch of drivers for a customer's Z80 controlled instrument
using the customer's TRS-80 as the development system. It worked just
fine, I guess... it got the job done, but I never did like it all that
much. I kind of liked the TRS80 IV, I think it was, that came out much
later.

Good for you! I really felt stupid seeing mine in the trash can only a year or two after having paid $300 for it.
Shoulda kept it? Nah.
Still have that little pocket version with 4k RAM, though. It'll come in handy someday :-)

The superregenerative receiver is usually used at VHF.

At HF, the regenerative receiver is more common. I built the WBR 40 meter
regen by N1BYT (QST Aug 2001) recently with good results.

Sorry, I never had much use for TRS-80's. But I do have a Commodore PET; a very original one (with the black tape deck). It has an IEEE-488 port, and a Basic that can control any IEEE-488 instrument. And, considering that it has a built-in monochrome monitor, it qualifies as a genuine boat-anchor, since it glows in the dark. <g>

A commercial calibration implies no warranty of future reliability. It just means that the unit was inspected, by a lab with traceable standards (to NIST), and that equipment parameters were found to be within the specified tolerances (or some adjustments we made to allow for proper performance).

Every equipment should be on a periodic schedule of calibration, possibly 6 months or 12 months. The interval is determined by the original manufacturer's declaration, or from the class of equipment (is it a resistor or a function generator or an oscilloscope), or from the accumulated record of a device's calibration history. (A Metrology professional can make a case for shorter or longer intervals, based on a review of the calibration history.)

The calibration is valid as of that date only, although it's reasonable to expect that the calibration will be valid for some time to come (unless the shipper dropped it as it went out the cal lab's door!).

All that said, a traceable calibration is an indication that the equipment has been treated in a professional manner, and I would view that as a definite plus when considering a purchase.

Sorry, I don't do watches. A "little optical help" isn't a magnifying lens in a fluorescent work light. SM work calls for something like a B&L stereo viewer, and that's as expensive as a very decent oscilloscope. BTW, turn on your spell checker, a 1980's technology.

> From what I have heard, most
> of the parts in the hybrid are standard off the shelf surface mount

Julian,

I do not know where you are looking.

IF you have an HF transceiver there are VHF transverters available from both
Ten-Tec and Elecraft

http://www.tentec.com/Amateur.htm

Elecraft will have a 440 transverter available in the near future
http://www.elecraft.com/XV/XV.htm

Hamtronics - VHF and UHF kits since 1962
Receive converter kits (less enclosure) are only $ 49 USD
http://www.hamtronics.com/

Fresh calibration, should mean that it was fully tested out,
cleaned and calibrated by a technician who knew what he was
doing....

What it actually means is anybodies guess. It could be actually
calibrated, it could be that the guy bought it surplus, turned
it on, and it lit up.

The words "fresh calibration" without an express warranty are
worthless.

Most anything Tektronix or HP made will stay in calibration to
close enough for hobbiest use for years.

A real bonifide business won't be comfortable using test equipment
that is out of calibration for anything very important. It is
their assurance that all of the functions should be working properly.

You should care. Unless you suddenly start building your own test
equipment, you are going to be "stuck" with using equipment geared
toward professionals, and manufactured by companies like HP(Agilent)
or tektronix.

OBTW, can you think of a less vulgar way of expressing your opinions?

I have no financial interest in any test equipment manufacturer. They
don't give me special favors, or punishments for stating my opinions.

The "average hobbyist" once made complete radios from hunks
of rock, metal and wood. A pretty extreme feat for the time.
Now if it requires a little study, or the acquisition of some
special skill, or tools, it is deemed impossible.

At least when I post, my spelling is the result of my own efforts.
Yours, apparently, comes from the efforts of a machine. I don't
think it hurt your eyes all that much to stumble over one of my very
few typo's. When you type at over 100WPM, a few will sneak in now and
then.

The parts in these hybrids are very large compared with mechanical watch
parts. A cheapy stereo dissection microscope works very nicely...
easily had for $250 new, or $100 on ebay. Back in the days of yore,
adjusted to today's dollar, a soldering gun cost as much.

You have some direct knowledge that says differently? I know that there
will be some parts that are special, but I doubt all are. I have
several friends that do a good business repairing these "special"
hybrids, they aren't great big companies, just individual hams that saw
a market.

I haven't needed to go inside the hybrids on my 2465, mostly because I
don't put my scope into positions where it is likely it will get zapped.

Or, better, Down-East Microwave in New Jersey. They sell kits for 50 MHz
and up, up, up.

http://www.downeastmicrowave.com/

Reliable outfit, reliable gear. They've been at it for many years.

> By the average hobbyist? I don't think so!!!!!!!!!!!

I work on SMD all the time. All that's needed is a 40W temperature controlled iron, a roll of good solder braid, and 63/37 solder with internal no-clean flux.
I go down as far as 0402 components, which look like sand, and have replaced 100 pin QFP chips without problem. BGAs are where the hobbyist becomes incapable of working on them. (Ball Grid Arrays)

Julian,

No, it is not particularly difficult to build for 144/432 MHz.
All you need are good low-noise devices, short leads and a little
determination, which I'm sure you have plenty of. For starters,
why not have a look at the simple 144 to 30MHz converter on this
site -

http://homepage.tinet.ie/~ei9gq/vhf_conv.html

This should give you an idea of the style of construction
needed. The only component that you may have trouble with is the
overtone crystal but there are other ways of achieving the same
end.

I found some jellybeans (LM318TC) with 10 MHz GBW product and I plan to play. Anyone have any tips for doing RF with jellybean ICs?

These might be a bit noisy for microvolt stuff, but I plan to start with IF frequencies and move on as the play permits.

Also, anyone play with the new generation of fifty-cent jellybean 100+ MHz amplifiers?

Those were pretty good thirty years ago, and even the late seventies, but
the LM318 is pretty puny at this point. Not only are there much better
op-amps, but you couldn't do all that much with the 10MHz spec (just more
than the 741 decades ago).

I really don't know the state of high speed op-amps today, but I think
I'd go directly to them if I needed them.

I have a Connex 3300 radio that i am willing to sell. The radio is in good working condition. It has a roger beep installed, with a switch for it on the right side of the radio. It also has a toy that honks a semi horn 2 time then says "Hey get out of the way stupid!". I have a road king mic for it. It will aslo come with a midland external speaker for it. The radio has Am/Fm band and PA. It has 240 channels.
I had it listed on E-bay and the auction was ended, becuase it is a problematic radio since it is considered a 10 meter radio. But if you are intrested in buying it feel free to E-mail me at "mrnmrscody@aol.com". The radio is about 6 month old, unfortunatley my house burned down sept. 26 and I do not have the original box or paper. Radio was saved since it was in my big truck! I hate to sell it but with everything going on in my life I am forced to sell it.

I've been playing with/using things like the OPA685, THS4302RG and
AD8351. I'll probably try the AD8099, but suspect it won't go low
enough in distortion at 40MHz. My holy grail is better than -80dBc
second and third harmonics at 50MHz and 2V p-p output, and
input-referred voltage noise down in the 1-2nV/rtHz region. But I
suppose that I'll never be completely happy, as the bar will move
higher as fast ADC resolution and distortion improve. As for ADCs,
I'm hoping for 18 useful bits at 100Ms/s in monolithic, and would
welcome 20 bits or more. We've done 23 bits at 20Ms/s for a long time
now, but it's a tad pricey.

Cheers,
Tom

I've built several GDO's over the years. My favorite circuit is the old standby using a split stator variable capacitor and a shunt fed coplets oscillator. This capacitor can be 100-250 pf per section. My favorite tube is the 6CW4 nuvistor, though a 6DV4 might
be a better choice at VHF. I put a TO-5 transistor heat sink over the tube fearing it might run hot! I use a cathode resistor of about 150-330 ohms (un-bypassed) and connect a bnc connector to the cathode via a 1000pf capacitor to steal a little signal to drive my frequency counter. With the counter set for low level input I get good drive up to about 100mhz or so. My coil socket is an RCA (phono) connector and the coils use a matching plug. A better idea might be to use a 3 pin DIN plug and socket, this allows for a ground connection to go to a coil center tap. If you add the center tap the circuit will work below 1.5mhz with proper coils, otherwise it will not oscillate below this frequency! (Having coils that go to 455khz would be nice to test if stages). Power supply used two 6.3v 300ma filament transformers back to back with a bridge rectifier. You can find transformers small enough to fit the supply into a box small enough to house the instrument, yet not too big to be hand hold-able. The coils can be wound on 1/4" or 3/8" plastic water line intended for ice maker use. These will fit into small places. Use of peaking chokes in the plate and filament lines can help eliminate "drop outs" in frequency coverage. Sensitivity can be adjusted with a plate pot, or put the pot in the meter circuit. I have used sub-mini meters salvaged from old jap tape recorders (vu-meters). These are typically around 500ua sensitivity. See my web site at www.qsl.net/wa2mze.

3700. Re: hi-speed op amps for RF?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-22 07:05:35 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <ftSdnQwjPL5QmSKiRVn-sA@comcast.com>
Source record: 30816

Clifton,

I've been exploring much the same concept. I hate having to figure the bias resistors for a transistor circuit, so I found op-amps fairly attractive to think
about using.

Here's a few things to consider:

1) Typical gains for RF or IF stages in traditional receivers start at about 20db,
that's a stiff enough gain to justify the noise figure inherent in an active circuit
stage. 20db translates into a gain of 10.

The shortwave band is approximately 2 to 30 Mhz. That means to cover the shortwave band at a 20db gain, we need a gain-bandwidth product of about 2 X 10 - 30 X 10, or about 20 Mhz GBW to 300 GBW.

Your LM318 won't cut it for shortwave.

2) Look at the latest circuits from Analog Devices, Linear Technlogies, or Maxim. They will provide samples if you are a qualified engineer, even if you
happen to be a consultant.

Today's circuits have GBW's ranging from 900 to 1500 GBW, at 10 Mhz (everyone's favorite band for CW) you're looking at a gain of 90 to 150,
or approximately 35 to 43 db.

30 db circuits become possible with these devices at 10 Mhz, so I would go with that range of GBW.

3) Op-amps created for different applications are useful in different parts of
a shortwave receiver. Voltage-controlled amps are good for tunable IF filters. Low-noise op-amps created for hard drive heads are good for preselector stages. Rail-to-rail op-amps are good just after the demodulator
as a form of automatic gain control.

4) Remember, op-amps have worse noise than transistors, all other things being equal. An all op-amp shortwave receiver is possible but you need
to not get carried away and paste every possible active device you can get your hands on.

5) Given a choice between an passive mixer terminated with op-amps and
an 4-quadrant multiplying active mixer, I'd take the latter. They have
a
gain figure that is quite hard to beat with an op-amp with far better
noise
figure.

I'd don't have any circuits to give you, this is what I have learned playing
with
high bandwidth op-amps in LTSpice.

Good luck,

The Eternal Squire

Can only agree very much to your comment "there is *no way* AFAICS
that the thing would be capable of anything remotely close to that
upper range limit", whether the upper limit is 280 or 360MHz becomes
less important when it actually don't operate properly above 140MHz

But I don't see that an instrument intended to cover down to 500kHz
could have practical variable capacitor for UHF, so somewhere should
be another construction. Perhaps an idea to look at DL7QY microwave
dipmeter.... I might consider copying some of his details to a web
page

You can use a capacitor in series with the variable capacitor to reduce
the tuning range, but you would need a switch to select the high or low
capacitance range, and to move the coil connection to the active
components. That, or use a dual capacitor, build two circuits, and
select one oscillator at a time.

a friend has recently suggested that i should use 2sc2570 for vhf
work. i got a couple locally, they are cheap too. i have been told
that they have an Ft of 4.5GHz. i have searched the web trying to look
for datasheets.
my transistor is marked NEC, but the NEC site doesnt seem to have any
data on this beast.
any pointers??

Hi
There are a couple of useful items in an article in "The VHF/UHF DX Book" - edited by Ian White G3SEK Which look as if one or the other might suit your application - one strip line, the other co-ax.
Section in the book is "Test Gear & Station Accessories - Impedance & VSWR Measurement" - A gold mine of information!
Hope this helps

3709. tda1572 oscillator configuration

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-22 20:03:42 UTC
From: Pete KE9OA <n.gianakopoulos@worldnet.att.net>
Message-ID: <yiPvb.311308$0v4.18332795@bgtnsc04-news.ops.worldnet.att.net>
Source record: 30826

Has anybody used the oscillator section of the tda1572 with a crystal type of configuration. I looked at the tda1072 application note in one of my old data books, and I don't see how that circuit would even oscillate. I know that it can be done, because the Linn Kudos FM/AM tuner does this with the chip's on-board oscillator.

I just acquired an HP 8640B and now I'd like to get rid of my HP 606A but I need to go below 500 KHz. I wonder if anyone has had any experience with the HP 11710A or B that they'd care to comment on. I'd also like to know if there's any other reasonably priced LF sig gen that's stable and has a calibrated output that I should consider as $150.00 for an HP 11710 seems kind of high when you can find HP 8640Bs for around $200.

3711. Homebrew DDS-based Scalar Sweep Set

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-22 22:43:53 UTC
From: W3JDR <joe@roccis.com>
Message-ID: <JERvb.2745$rS5.357@nwrdny02.gnilink.net>
Source record: 30828

I've been working on a very simple and inexpensive HF Scalar Sweep set for testing filters and other frequency dependent devices. It's based on a DDS frequency source and an Analog Devices log detector. Sprinkle in some PIC firmware and some Visual Basic software, and you have a very nice little RF test instrument that rivals equipment costing much, much more. If you want to see where I am, you can get more info at my web site:

http://mysite.verizon.net/jdrocci/index.html

I have a lot of ideas for expanding the capability of this device. With some outboard modules and appropriate software, it could be an HF spectrum analyzer, a return-loss analyzer, an accurate RF probe, and a lot more. I'm looking for constructive suggestions.

Source record: 30829

I've been looking at building a few vacuum-tube based projects (just for the heck of it...and maybe use a few of the tubes I have siting around! :)) I have been able to acquire a few single-winding transformers, both HV(175-250 V) and either 6 or 12 for heaters
Question: since I do not have the dual-voltage transformers in a single package, when wiring them into the circuit, are the 117V primaries wired in series? This SEEMS correct, but my suppositions have been wrong before!

Probably not, but there isn't any disadvantage to using a tube, except
for having to use an AC operated supply. If you need a portable grid
dipper (to check antennas up on the tower for example) then you want a
solid state battery operated unit (which sure beats 100 feet of
extension cord dragging behind you when you climb the tower!).

Not all fets function well into the vhf range. If you want to build a
solid state dipper using fets make sure you get vhf units, not ones

intended for audio use. There are circuits using fets that simulate
negative resistance (like tunnel diodes) which make for an interesting
oscillator since no coil taps are needed and a single gang cap can be used.

I assume you mean using two transformers, one for the hv and one for the heaters. You must wire the primaries in PARALLEL NOT series! If you want to operate the thing on a 240v line then you need to get two identical transformers, put the secondaries in parallel and the primaries in series (total of 4 transformers in this case).

Thanks for the quick response. Yes, I plan to use 2 seperate transformers...and will be VERY mindful of the caution needed when working with high voltages! I caused enough trouble at work last night when I added the wrong chemical (a concentrated detergent) to a chemical bath...there was this pretty purple foam flying about, though... :)

Right. I don't like fets, execpt as switches, RX RF amplifier and in
PA. We had a discussion in a radio club among designers 30 years ago
if it was any reason for using fets in oscillators instead of
bipolars, but couldn't really find any good reason, except they were
fancy.
It is also a circuit using a jfet and pnp-combination which works in a
negative impedance mode, but usually found on lower frequencies. Used
it for some time to check resonnant frequency of unknown tuned
circuits with a counter, but the problem is to control oscillation
level. It worked fine for 50% of the applications while the counter
indicated some higher (or lower) frequency for some circuits, so it
was abandomed. Believe I have seen it mentioned for griddipmeters,
too.
It seems to be a reason why PNP UHF transistors are used in most UHF
tuners found here, usually BF479, BF679, BF979. I've copied some of
the text for DL7QY's dip meter covering up to 1400MHz on
http://home.online.no/~la8ak/m3.htm

20-30 years ago TBA120 (Texas SN76660N) was a popular device and used
in several numerous applications in Europe, particularly in Germany
and Nederland, some of these constructions were published in the
"Elektor" magazine (believe the original was Dutch),
among the applications I remember:

RF mixer
phase detector
product detector
audio mixer
oscillators on audio as well as RF
syncronous AM detector
etc
It is no real principal difference between devices like TDA1047,
TBA120, NE/SA604, NE614, TDA1576, TBA120, S041P, MC1357P so if you
have the schematic of the inner functions, find the phase relation
between the limiter input pins and quadrature output connections you
should be able to make an xtal oscillator

I wrote some note to Radcom (G3VA) about TBA120 applications 20 years
ago, but cannot remember today which applications I tested, believe it
was found a maximum frequency around 15MHz.
The later devices are designed for low-power with low maximum
frequency, while the older like Motorola MC1357P (not MC3357) has been
used as 70MHz ATV demodulator and was published in such magazine
around 1984, one MC1357P was also used as RF limiter. But if your
device is a low-poer-type, it might not operate at high enough
frequency where you have an xtal to connect.
Believe I have some applications on one of my pages, but lack the
index, so I'll have to use google to search on my own pages, hi

The negative resistance fet circuit I mentioned used a pair of jfets,
one P channel and one N channel with the sources tied together and the
gates of each transistor tied to the drain of the other. In this way
each transistor acts as the self bias resistor of the other. The
resulting voltage/current curve of the combo exhibits a region where the
current decreases as the voltage increases, looking much like the 'kink'
in the plate circuit curves of an old time tetrode tube (such as the
24A). The major disadvantage of this circuit for a gdo is that it is

such a strong oscillator that you don't get much of a dip (you need to sample the output and feed it to a rectifier and meter) unless you load the coil down with a shunt resistor....and you need a different value for each range. Also P channel fets with good vhf performance are as rare as hen's teeth.

ed ...what is a tracking generator and how is it a advantage for a
home hobbyist to have one or is it really necessary? also what do you
thing about 8565a's

also what is the determining factor for pricing on these various units
on ebay? does it have anything to do with the options on each unit?
sometimes there would appear to be some flucuations on the prices on
either the same type unit or a similar unit.

A tracking generator is a sweep generator calibrated to track
to the center frequency of a spectrum analyzer as it sweeps.

Got it?

It is used to display the bandpass characteristics of a network
using a spectrum analyzer.

Exactly. I found the 8556 plug-in, with a range of 20 Hz to 300 kHz, to be very handy when I was designing lowpass EMI filters (which usually have a cut-off frequency below 10 kHz or so, and increase in loss to maybe 60 dB by 100 kHz. The tracking generator could give me a quick look at the cutoff and slope, so I could tweak the circuit in real-time. It's also handy for acoustics, ultrasonic and vibration testing.

And the 141 has a plotter X & Y output, so you can drive an analog plotter to trace the curve using a very slow sweep speed.

Just a thought, my 5gal stainless steel Cornelius kegs would
make great hi Q VHF resonant cavities but the only way I can think of
tuning them would be to vary the beer level by drinking it. However if I
was having a lot of QSOs involving a lot of channel changes then I would
be forced to drink a lot of beer .... and consequently not capable of
having a coherent QSO 'cos I make very good beer ..... on the other hand
I could stay fixed frequency but not be able to drink the beer ....
Ah well, back to the drawing board !!!!!

<< I just acquired an HP 8640B and now I'd like to get rid of my HP 606A but I need to go below 500 KHz. >>

Hank-

Recently someone mentioned that the 8640B was a UHF signal generator that had digital dividers for lower frequencies. If that is true, you might be able to add additional dividers to go lower in frequency. You might have to sacrifice one of the existing bands, depending on how extensive the modification is.

Interesting. The circuit I rebuilt my old Tradiper with used two
dual-gate MOSFETs., 3SK88s I believe they are. It gives a nice fragile
ouput which is easily pulled down by an external tuned circuit,
thereby giving rise to a good, deep dip. The only problem is the size
of the blasted snifffer coils! Whilst this is fine for big old valve
type constructions, it *is* totally impractical for today's ever
smaller PCB jobs. I guess the time is coming to abandon it in favour
of some other method of measurement, probably involving a scope and
sig-gen.

Does anyone have some 3 inch coil stock (10tpi, about 10-12 inches long) they'd be willing to sell?

Also need a 1200pf variable capacitor (100 watt level spacing) and a dual 200 pf per section variable (also 100 watt level).

Am building a link-coupled 160 meter transmatch per a very old Lew McCoy article.

thanks

To get lowband out of an 8640, I think I would simply add a mixer to the output of the 8640.

Get a cheap oscillator, one of those computer time base ones, and feed it into the LO of a double balanced mixer. SBL-1 or some such.

Feed the 8640 into the RF in and then you have your desired lowband on the IF output.

==========

I'd add an attenuator to the IF output pin, 4 dB.

This way, assuming about 6 dB loss in the mixer, you know the output is just about 10 dB below what the 8640 output level is and you can use that to set the lowband output to a known level.

Make sure you read the data sheet first if you're thinking these might
make good general purpose amps! Those MMICs are only for the cellular
frequency range--minimum freq of 800MHz.

Thanks.....I appreciate the info. I finally found an application circuit, but using the topology that is described, the circuit behaves more like an LC oscillator vs. a crystal oscillator.
This chip must have been designed by a different enginnering team, than the one that did the NE602. The mixer is a real joke, with its 200K output impedance vs. the 1.5K output impedance of the 602. The 602 uses an emitter follower type of oscillator, while the 1072/1572 us a hard to implement differential oscillator. The 602's oscillator is good to 200MHz, while the 1572 is limited to 50MHz. Now I understand why AOR chose to use just the I.F. subsystem/demodulator sections of this chip. I think that I am going to go with a 602 for the 2nd mixer, and use an AGC loop ahead of it.
On another note, things are moving ahead at a good rate on the MW receiver design. I've completed the synthesizer, and am now working on optimizing the step response. Reference sidebands are -80dBc, with 2nd, 3rd, and 4th harmonics at -28dBc, -43dBc, and -60dBc respectively.
I entered the system of loop filter equations from Motorola's AN1207 appnote into an Excel spreadsheet, eliminating the need to spend a half hour muddling through those equations. I did discover three errors in that appnote, so be careful when using it.
The selection of R2's value was shifted over one decimal point, while the value of omegaB was slightly off. The equation for C5's value used an incorrect value for R14.
Overall, the real problem with this appnote was one of carelessness; apparently, nobody proofread the document before releasing it for publication. I don't think that I've ever seen so many errors in this type of document, which is why I wonder about the accuracy of that Philips appnote for the 1572.

Source record: 30757

Found some notes in last Radcom (Technical topics by G3VA) about
saturable core inductors. Surprising little has been discussed about
the matter recently, but I suppose it could be a good idea to use for
LF experiments when tunable cores are a problem, he also mentions
using two MOSFETs to form a variable capacitor with maximum
capacitance of 1500pF

see http://home.online.no/~la8ak/c97.htm for some more info extracted
from Tecnical topics 11/2003

I've had good luck using solder paste (not TOO expensive from digikey,
especially considering how little of it I use at a time). I use it with
a small soldering iron, a butane pencil torch, or the toaster-oven method.
(I use an oil lamp instead of a toaster-oven, but the technique's basically
the same.) I apply the paste with a toothpick and then melt it with one of
those three tools. I've had no trouble soldering SSOPs or 0805 chip
components.

The one easy mistake to make, I've found, is not to preheat the board long
enough before trying to solder using a hot-air torch or oven. The liquid
components of the solder paste will boil suddenly and pop the component right
off the board.

As other people have mentioned, once you get the hang of SMT soldering,
it's really nice not to have to drill so many holes in your prototype
PCBs any more.

I don't think you would get an oxygen-free environment very eaily
that way. I think it would be easier to fill the box with some inert
gas rather than trying to draw a vacuum.

John,
Thanks for the compliment!

Yes, I have read Paul's work. Although the vector capability would be nice (especially for antenna work), I didn't feel I need the added complexity for an HF only unit. I wanted it to be KISS-like so I could get it going fast and begin using it for what it was intended. Besides, Paul's software seems to be written under DOS, and I don't think he's offered to open the source yet. Also, programming a rectangular grid is very easy. The thought of programming a polar Smith chart makes my brain matter smoke.

Next step for me is to put it in a housing with its own power supply and develop some hardware calibration routines for flatness, scale calibration, etc. It's been fun.

A good enuf approximation would be to double the width for the 1/16" board --
gives 5.6 mm when using 1/8". The Zo is a function of the w/h ratio [not
exact, but close enuf for anything you would be using G-10 or similar for].

If you scale all the dimensions of any TEM line, the impedance will
stay the same.

Also, I have an Excel spreadsheet that lets you find impedances (a
free download but I don't have the URL handy...), and there are
several stripline/microstrip applets on the web...should be easy to
find with a Google search. Perhaps the best answer is to use the
transmission line calculator in RFSim99, which is free and does a
whole lot more than just transmission lines.

Cheers,
Tom

It's part of a design for a T/R sense circuit for a noise cancellation device.

I won't bore you with too many details. One thing I noticed in a design I'm looking at is that 1W resistors could be subject to as much as 50W of power apiece during the time it takes for a relay to respond. This response time is 7msec. The overall duty cycle will be low (well under 1%).

Can the 1W-51 ohm resistors handle this 50 RF volts 0-peak (about 50W PEP) for .007 sec? 50W over .007 seconds is .35 Joules. .35W for 1 second is also .35 Joules, which a 1W resistor should have no trouble handling. Can the resistors be damaged during that .007 seconds?

Also, how much time does it take to damage a toroid? If it can handle X units of flux density continuously, how much flux density can it handle for .007 seconds with a low overall duty cycle (like well under 1%)?

Hi. I've always read upto 10x the rated diss is workable. 50x is
really pushing it I would think. My experience with this is limited
though - but I can tell you from experience that 1500x rated power
doesnt work so well :)

Regards, NT

But what happens if the relay fails to close in 7 mSec? OOPS!

Or fails to close at all? BIG OOPS!

Many years ago I analyzed a problem with resistors which were
discoloring in the field. This involved two identical circuits with
identical singal inputs. In one circuit, a resistor kept turning brown
over time, in the other it did not. We were getting field returns as a
result of troubleshooting that focused on the brown resistors.

What was the difference? The resistor which did not discolor was resting
on two metal traces which ran under it, the one which discolored, was
resting on the PCB. That tiny amount of heatsinking provided by the
traces was the difference. Obviously, the circuit needed to be
redesigned, but it worked great on the breadboard when it went into
production.

I have here some datasheets of Beyschlag MELF-resistors (CMA0204). They take up to 40W continuous pulses if the pulse length is 200us or shorter. So 2-3 of those should be able to absorb your pulse. They also have non-inductive types for RF-apps.

Your question is improper- no mention of resistor type - almost any
resistor type can take the limited overload if you up the steady state
power rating. When in doubt go with bulk ceramic- these products are
well characterized for pulsed overload operation and used in RF apps.
http://www.globar.com/ec/resistor.php.html

This will be easier because the heating time constant is longer and RF
is reflected away when it saturates- you will have to measure this
yourself- it is unlikely any manufacturer has done it.

Depends on the resistor's construction. It is a rating that will be published in the mfr's data sheets. Cement-coated resistors have a low peak stress rating. Enamelled and welded wirewound, composition and ceramic resistors can have high pulse power handling capabilities in a single surge event that is characterised as being less than a half cycle of the AC line frequency (a common surge stress rating).

Toroids are basically thermally limited to their material construction class. If wire doesn't fuse, the em force applied doesn't cause mechanical damage and you don't care if volt-seconds are exceeded (saturation), a 7mSec overwattage isn't going to hurt the part permanently.

The resistor should never have been run at that close to its maximum
dissipation to begin with. That's a lack of what they call a
conservative design.

That's exactly right-and this story about "it worked right during production testing" points up the fact that the price you pay for misapplying a component is extended in-house testing designed at a higher skill level than the usual application engineer possesses.

True, but -- while relays aren't exactly that horribly reliable,
long-term -- for transistor-driver applications it's not at all surprising
to see components used that would fry if left on full-time. For instance,
you often see drive transistors for the ringers of cell phones that would be
operating above their rated specs if they were turned 'on' 100% of the time,
yet such a design is still practical for the sake of cost savings and
miniaturization in a that type of product.

Resistor pulse ratings can be difficult to obtain from manufacturers. As stated by another poster, peak power ratings on datasheets are often about 10x continuous, sometimes even lower. For high value resistors, the voltage across the resistor may be the limiting factor. Anyhow, I've destructively tested lots of low value resistors. For some intermediate range of pulse durations, their failure point tends to follow the famous 'I-squared-t equals K' curve, which describes the ideal tradeoff between time and power level. At some short pulse duration, the failure threshold becomes roughly constant. The resistor reaches a power density that causes rapid destruction of the conductor. For wirewound and metal oxide resistors, this power level can be 100s of times the average power rating. For carbon composition resistors, 50x may or may not be destructive. Carbon film and thick film resistors have failure points that vary all over the map. This is partly due to the way that they are trimmed: scribing or laser cutting produces a narrow area in the resistive element, which concentrates power in a small zone. Failure is usually due to cracking of the element as it expands more rapidly than the substrate. This is why pulse ratings for these type resistors are usually very

low multiples of their continuous rating. So, it depends.

Hi Group,

I have a phone-cell just like alot of hams which gets free service over the weekends and after 9 pm on the weekdays. I also spend alot of time on the road. I have tried HF mobile but it just not like the base with the car noise and weaker signal.

Has anyone designed a phone-cell interface so that I can call my home number and connect up to the HF or VHF rig?

I would be interested in hearing about any cell phone and ham related projects.

I saw in the application notes for hp that for extending the range,they use dividers with filters.
An other example was the use of the 5 MHz output as lo for a mixer.
Then use the generator in the range from 5 to 5.5 MHz and feed this also in a mixer.

Absolutely a good, pragmatic answer, Bill. MANY components can
survive a very short power overload. Carbon Comps do.

A "sacrifice" test can be done with a DC power supply, an electrolytic
capacitor, and a switch. Charge up the electrolytic, then dump the
charge through the resistor. It should be a trivial thing to calculate the
"pulse" of the initial charge-dump through the resistor for any under-
or post-grad engineering type...for a particular resistance, capacitor,
and voltage.

A rough time-constant of t = R x C yields the "pulse" time. Figure
the "pulse" power as half the capacitor charge voltage across
the resistor under test. Not precision, true, but pragmatic and
quick.

If it doesn't survive, well, too bad. [sacrifice]

If it survives, try it several more times, noting appearance, resistance
before and after each "pulse" test.

...or, everyone else can spend a lot of time at "intellectual arguments"
in here without ever trying it out on the bench... :-)

Yes, it uses digital divide-by-2 stages, but to get low harmonic
content in the output, the square wave is filtered by some pretty
decent filters. I don't know what the going price of things like the
HP3325A is, but that's a decent generator with very good frequency
resolution. For the low frequencies involved, you could also just use
a DDS, followed by a switched attenuator. A mixer down from higher
freqs is OK if you don't care about phase noise, I guess; add a LPF to
get rid of RF and LO feedthrough. You do miss one of the nice things
about the HP8640B, though, which is high output power. Getting back
to +20dBm with op amps shouldn't be too hard, but to keep SNR good,
you'd want to follow that with a step attenuator anyway (or take the
amplifier out of the circuit), probably, and not rely on just the 8640
output level to do the trick at really low levels.

Cheers,
Tom

3770. RS DX-394B: why 2nd LO buffer added?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-26 02:14:09 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <M_Twb.7948$Eq1.987002@news20.bellglobal.com>
Source record: 30786
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.shortwave

Apart from the new pcb, the main electrical difference between the Radio Shack DX-394B and its immediate predecessor, the DX-394A, is the addition of an emitter follower buffer amp between the output of the 2nd local Oscillator (the emitter of the one transistor 44.5MHz VCXO) and the 2nd mixer. The latter is a 2SK210-Y/YY VHF N-channel JFET; 1st IF is injected at the gate and the 2nd LO at the drain.

Why would the designers add the buffer? What performance comparison should I make between the A and the B model to assess whether it would be worthwhile to retrofit a similar buffer to the A model? I can say that I have not noticed any dramatic difference with my usual listening habits.

Tom

Why bother with MOSFETs? You can get varactor diodes used for tuning
AM broadcast receivers with that much capacitance.

I worked for a small company that was owned by a conglomerate. The
conglomerate said that they'd never use any of our equipment that were
in a blue case. Which, since almost everything was in a blue case...

Anyway, we had problems with the 7805 regulators shutting down from
overtemp. They were mounted on the PCB with a small heatsink. So we
had to ECO them by adding a few inches of wire and bolting the 7805 to
the aluminum case, which soaked up plenty of heat. After that, no
more weird behavior.

3775. Follow-up: Car battery charger

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-26 06:03:11 UTC
From: "Bruce W...1" <bruce@noDirectEmail.com>
Message-ID: <3FC4421F.61BDE4DA@noDirectEmail.com>
Source record: 30791

Not long ago and in another thread many of you gave me great advice on how to make a car battery float charger. I wanted to just connect a properly sized wall wart, but everyone recommended voltage regulation. So I connected a voltage regulator (13.6V) to a 500mA wall wart. The wall wart has an open-circuit voltage of 18V and is rated 500mA at 12 V.

Further background, I built this charger to prevent my having to start a friends car once a week while they're on extended vacation.

Now two weeks later I check the battery. Its voltage is 12.7V. The charger circuit measures 13.7V. And I measured the drain, from the alarm and radio, it is 10mA.

The ambient temperature on average is about 40F.

What went wrong? Why is the battery only 12.7V instead of 13.7?

Lacking a better solution from you guys it seems we need more power, ugh, ugh. 2A ought to do it.

Spec's say that car batteries (at room temperature) are best regulated at 13.3V. For 32 degrees F 14.2V is better.

Yet the failure analysis remains incomplete. Where did we go wrong?

Thanks for your help.

What is the capacitance tolerance for such varactors and what is the
temperature coefficient ? These can be quite a problem in any
oscillator circuits.

To get such huge capacitance, the control voltage must be quite low.
In LF receiver front ends, the total RF voltage from any decent sized
antenna can be quite large, modulating the varactor voltage and hence
capacitance. This sounds like a varactor multiplier :-). Such
behaviour would not be so nice from intermodulation point of view.

In the worst case, the varactor could even be driven into conduction
due to a large applied total RF voltage, so a pair of back to back
varactors would have to be used. But with two capacitors in series in
the resonant circuit, the capacitance drops to one half of a single
varactor capacitance, thus, you would have to use two pairs of back to
back (4) varactors of 1500 pF each to get a total 1500 pF capacitance.

Even a larger number of varactors would be preferable, so a higher
minimum voltage could be used, with less risk for RF generated tuning
voltage modulation, but then the minimum capacitance would also
increase due to the limited maximum tuning voltage characteristics of
the varactor maximum available tuning voltage supply. I guess that the
larger varactors are quite expensive, so this would also limit the
number of units.

Switching in some fixed capacitors (e.g. in a binary sequence) avoids
some of these problems, but it would be quite hard to operate the
circuit with a large number of fixed capacitors.

Although that receiver is a broadcast-all-frequency portable radio, I think that this info could be of some interest to homebrewers and especially beginners. Many young future amateurs often ask me where they could buy a good amateur-band receiver. However, all the devices in the market today are transcievers, which are quite expensive and you must have a licence, too. So, I could not give them a satisfactory answer. I usually recommend some kit and my technical support, but this seldom works. The other day I had an opportunity to use a Sony ICF-SW7600GR receiver, and I was pleasantly surpised. The receiver is a double conversion superhet; it has all amateur bands, SSB mode (USB and LSB), CW, a BFO and an attenuator in the antenna. The VFO is a PLL covering all frequencies between 150 kHz and 30 MHz. There as a key-pad where you can type in the frequency, but after that you can change it in 1 kHz steps up and down by means of four press-buttons in the lower right-hand corner of the receiver. Finer tuning is easy with the BFO. The sensitivity is about 1.5 microvolts, and the selectivity about 4 kHz. Since the CW signal is strictly one-sided, it is easy for a homebrewer to add an active AF CW filter, if he thinks it to be necessary. I use the RX also as a precision and very sensitive frequency meter for the HF oscillators I build.

I think that SWL listeners, and QRP TX builders could use that receiver. Since the RX has been catalogized as a general consumption produce, it is easy to order it with any Sony seller. The price is about 170 dollars. This is not an advertisement, because I have not any connection with Sony, but I believe that this info will be useful to amateurs. I have been licenced since 1953, being a half-century homebrewer, and I am glad that I could find such a product in the market. You can find something more about it at <http://stephan.win31.de/sony7600.htm>.

You can also read about my Tayloe homebrew receiver at <http://www.hanssummers.com/electronics/gallery/4/>. Best wishes, Bozidar, 9a2hl

Yes, resonant frequency will change. To maintan the resonant frequency you need to shorten the thicker diameter elements.

They obviously wanted to provide some isolation and/or impedance
matching between the oscillator and the mixer. It's a good engineering
practice, but may not have much practical effect. If you don't notice
a difference, then don't bother retrofitting.

Also:

If the maker's specification says "2.5 times overload for 3 seconds",
don't figure that 3 times overload for 2.5 seconds is ok too.

Watch out for the voltage limits as well as power limits. With high value
resistors it is sometimes the voltage that limits you.

With SMT parts, all limits only apply if the part in mounted the way the
maker expected.

> oscillator circuits.

The tolerance of AM BCB varactors is extremely tight,
since the front end has to track with the LO in the radio.
Certainly far tighter tolerance than unspecified MOSFETs.

The tempco of those varactors is very low. Probably better than
any inductor you are going to resonate it with. In the low
100's of PPM.

> To get such huge capacitance, the control voltage must be quite low.

No it's not. The tuning voltage range is at least 10 volts and often
higher. At least as high as the breakdown voltage of the gate
oxide in a MOSFET.

> varactor capacitance, thus, you would have to use two pairs of back to
> back (4) varactors of 1500 pF each to get a total 1500 pF capacitance.

You can get several thousand pF in one diode from Toko. 1500 pF is
by no means the limit.

. I guess that the
> larger varactors are quite expensive, so this would also limit the
> number of units.

No they're not expensive. Consumer electronics manufacturers
buy them by the millions at low prices.

Recent visits to my local Radio Shack for even the most simple components has left me disappointed. Recently I had the need for 5 10uf electrolytics at any voltage really, and could not find them at 3 local stores.

There used to be a selection of 25 or so IC's that were widely used and popular...no more tho.

Even a simple LM386 could not be found around here.

Also, the parts are now being jammed into these ugly parts bins as if to hide them from view.

Is this the same situation where you live?

One manager mentioned that components are no longer a real concern of management and that he is under the impression that "parts" are on the way out soon.

Wouldn't that just be the way...the old local electronics places are out of business, and the Shack eliminates their parts. They sure do have answers, don't they?

I really doubt these varactor diodes are much good for tuning a transmitters PA? I don't want to go into retyping all the pages from G3VA, but the circuits are still shown as noted in the first place at http://home.online.no/~la8ak/c97.htm , you need some amount of mosfets to build a 10nF variable capacitor, but it is realisable. Don't know about other types mosfets than the mentioned ARF446/7 and APT10050, I got some hundreds IRF630 for nothing on a Scandinavian VHF meeting......
Technical topics, Radcom December 2003 pg 71 (G3VA): The note is based on "Frequency-Agile Class-D Power amplifier, by Frederick H Raab and Daniel Ruppe of Green Mountain Radio Research Company, and was presented at recent IEE HF Conference at Bath University. It describes (IEE Conference Publication No.493, pp81-85) an electronically-tuned class-D power amplifier that addresses the simultaneous needs for efficiency and frequency agility.

Since the yanks probably wouldn't accept any ideas from the ozzer world, I can enlighten you that Dr Raab is WA1WLW

I wonder what their answer will be when the cell phone market is saturated. (which is starting now) I really doubt that the Shack will survive, since they've pinned so much on cell phones.

The oscillator is an emitter follower, too, so I doubt that impedance matching is the objective. What would the increased isolation achieve? Would it preclude mixing of 1st IF energy in the oscillator? Should this be of some benefit for intermodulation products?

3799. would like advice on idea for class E SSB Exciter

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-27 03:45:49 UTC
From: The Eternal Squire <eternalsquire@comcast.net>
Message-ID: <J8idnb4eZ6nw8FiiRVn-gw@comcast.com>
Source record: 30715

Hi,

I'm considering making a class E amplifier for single-sideband output, but from what I understand, modulating the plate voltage produces double-sideband. I'd like to avoid that if I can.

I'm thinking of taking regular audio, digitally processing it into single-sideband using a soundcard, and then digitizing that to 8-bits.

I'd then create 8 class E amplifiers that put out 1/8w, 1/4w, 1/2w, 1w, 2w, 4w, 8w, and 16 watt outputs for the same signal; modulating each one as CW in accordance with the audio bit.

I'd combine the outputs through a power combiner.

Questions:

1) Would this scheme be possible for creating SSB by parallel switching of CW amplifiers in accordance with a digitized audio signal?

2) Would I need to create assymetrical power combiners to combine the amplitudes of the different signals, or could I get away with simply making a symmetrical 8-way combiner.

Thanks in advance,

The Eternal Squire

Yes, the few stores around here have stuffed the few parts into those cabinets. I don't think they are that bad, I'd like a couple dozen for my shop here at home for bigger parts. I have 25, 50 drawer parts cabinets already full of parts, but the drawers are too small for rotary switches and large connectors. Maybe they will pitch them out if they drop their remaining parts. There are six stores within an hours drive.

3802. Re: Follow-up: Car battery charger

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-27 04:52:10 UTC
From: Rick Frazier <rick@rickfrazier.com>
Message-ID: <3FC582FA.AF2439F7@rickfrazier.com>
Source record: 30719

Bruce:

Did you measure the voltage with the charger connected, or after you removed it?
A standard 12v lead-acid automotive battery has a nominal voltage of 12.6 volts. Even after a float charge, once the charging current is removed, the battery will return to about 12.6 volts fairly rapidly. Thus, the voltage you measured would be considered normal for a charged battery.

While the trickle charger is connected to the battery, any current in excess of that needed to fully charge the battery is converted to heat. You will only read the charging voltage when the charger is actually connected and operating. about 10ma of the current is going into the loads you've already measured, with the rest going to keeping the battery at top charge.

Unless you are measuring the voltage with the charger connected, you probably don't need to have one with more current.

Not an expert on instantaneous surges in resistors (you could ask my daughter - she is in third year physics ;-) but I would suggest that you consider using Flame-Proof resistors in this application. these are resistors that open internally and do not burn up your board when they fail...sometimes known as a fuse resistor....

Check for wire wound resistors, they are most likely to be capable of a high
pulse of current. But check for the manufacturers specification on what
they have been tested to tolerate.
There used to be several sources of these, but I haven't used any for years.
Of course a insulated bobbin with copper or iron wire could be used, if size
isn't critical. Wind it as a single or double layer to get the heat out.

3805. Max nr of poles in CW-filter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-27 08:34:07 UTC
From: Heikki Ahola <heikki.ahola@vtt.fi>
Message-ID: <3FC5B6FF.24DA9D66@vtt.fi>
Source record: 30721

Having built several ladder filters for SSB (8.. 10 MHz, 4 .. 8 poles)
with BW abt. 2 kHz (mainly for TX applications) I would like to try a
narrow filter (BW 500 or even less). One thing I am worried about is
the insertion loss. Has anyone any experience regarding the maximum
number of poles (= crystals) in such narrow filters. I have seen designs
for SSB with 14 poles but some doubts exist if this would be excessive
in a CW filter.

3806. Re: would like advice on idea for class E SSB Exciter

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-27 12:32:23 UTC
From: W3JDR <joe@roccis.com>
Message-ID: <r9mxb.1537$i81.663@nwrdny02.gnilink.net>
Source record: 30722

In concept, it should be possible to generate SSB digitally at any frequency and any power level. Clearly, it is possible to generate low-level SSB with a PC sound card, but the output frequency is typically limited by the speed at which the card can sample, digitize and process the audio. This speed limitation caps the output at around 15-20KHz with typical sound cards.

The output power delivered to the load is purely a function of how much voltage the D-A converter can deliver to the load. If, as you suggested, one took the 8-bit digital signal (pre-D/A converter) amplified each bit in 8 binary-weighted 'lossless' voltage (not power) drivers, and summed the output in a purely resistive load, then one would have a high-power, high efficiency SSB exciter.

Here are the problems I see:
1) Speed. The A/D, DSP, and D/A have to be able to process audio samples at twice the highest RF output frequency (2.5-3.0 times in practicality)
2) Precision: The high power weighted binary output drivers need to produce very accurate voltages
3) Spectral purity: The output spectrum will have aliases and 'birdies'. The number and amplitude of these is a function of the number of bits in the digitizing process, and the accuracy of the high-power D-A at the output.
4) Complexity: Enough said about this.

A more practical way to get a similar result might be to generate low-level SSB in a high-speed DSP, and amplify the analog result it in a class-B amplifier whose bias is dynamically adjusted by the DSP processor in anticipation of the instantaneous RF level. This should produce a highly-quality signal with good overall power efficiency.

Most of the components below are still available.
Some of the quantities have changed. E-mail for
details.

I would add Allied www.alliedelec.com to that list -- their "break point"
for shipping is $25, they will ship via USPS Priority Mail (which is very
quick anyway). At any rate, who doesn't have a soft-spot in their heart for
old Allied with their Knight Kits from 4 decades ago!

nope, you will instead need to apply simultaneous frequency modulation
to the carrier as well as amplitude modulation.

> 2) Would I need to create assymetrical power combiners to combine the
> amplitudes
> of the different signals, or could I get away with simply making a
> symmetrical
> 8-way combiner.
>

you will need an infinite way combiner, the easier way is to frequency
modulate the carrier so that it shifts to wherever you want the
carrier to be and control the envelope (this is a white lie, the
acutal explanation is a little deeper).

the dsp software required is not going to be easy. i have written a
dsp shell for the sound card, you can download from
http://farhan.net.co.nr and play with it. once i am finished with my
VHF transceiver i plan implement a hilbert transform using this shell
and make a simple SSB exciter with it.

I agree with BIll,

http://www.mouser.com has online pdf catalog, same day shipping fast.

http://www.allcorp.com has some good stuff also.

Try Digi-Key or Mouser Electronics on the Internet. You can't get much more convenient than that. A few "clicks" on the their web site and 3-4 days later the parts are setting on your door step. It beats driving all over town.

==========

The battery measured 12.7V both with and without the charger connected.
So the charger (putting out 13.7V and 500mA) doesn't have enough juice,
er current, to change this. So right now 500mA is being converted to
heat.

This begs the question, what then is the point in regulating the charge
voltage to 13.3V (or 14.2V at freezing temperatures)? Wouldn't a
charger regulated at say 12.9V do just as well at keeping a full charge?

This comes full circle on my original thread postulation. There is NO
point in regulating the voltage, just connect a properly sized wall wart
and you're done. The proof is right here.

This is an entirely different situation. The maximum flux density is
fixed by the core material, and cannot be exceeded, no matter how much
current you feed through the coil.

The last time I went to rat shack the two salesmen staffing the store
descended on me like a pair of hungry vultures...when they found out I
wasnt there to buy a phone or oher electronic appliance they left me
alone. Its odd how rat shack has confined all parts to the parts bin
thing yet they sell new soldering irons and those junk tools.......
This store does seem to keep an adequete supply of their ferric
chloride in stock hough, that and he odd connector are all I buy
there.

The electronics supply house we had here, radio electric, left town
many years ago....we do have another elecronic place in a nearby town
but it sells mostly computer and telecommunications related

stuff....Th ics they do carry are all nte at nte prices.....and the selection of passives is poor...like rat shack kind of 5 resistors for a dollar something........

I honestly hate having to use a place like mouser or allied but what else can you do ???

That means that there is 100 Ohms between the PS and the battery. It's likely that this is the resistance of the meter that you used to measure the 10mA, and that the actual current without the current meter was more.

But I still don't understand how you could read 13.7V at the PS and 12.7V at the battery unless there is a significant resistance between the two. Note that this resistance could be in the ground leg, too.

OTOH, holding the battery voltage at 12.7 will be just fine for long term storage. Higher voltages will keep it topped up at full charge, but they also do some long term damage and convert water to hydrogen and oxygen via hydrolysis.

You're really better off at the lower voltage, and 12.7V is just fine.

I strongly suspect that a wire-wound resistor is totally
unsuitable for this RF application.

>
> Thanks for your help.

I don't know how you measured things - so I can't say for
sure - but you may not have a failure.

1) You need to measure the float charge voltage while the
charger is charging the battery. Don't know if you did that,
but 13.7 is good if you did.

2) The battery needs to be fully charged before connecting
the float charger. Don't know if it was. If the battery is
discharged and you connect your float charger and measure it,
you will see a voltage below 13.7 A discharged battery can
draw enough current to drop the output voltage of the wall
wart down below the 13.7 regulation voltage.

3) A battery removed from the float charge will show a lower
voltage than the float voltage. That is normal. So it is

possible that your charger is working properly and the battery
is being held at full charge.

Use the pipe, all other conditions being equal.

Whether hollow or solid, the larger the diameter, the
better off you are for that antenna. It is not a
thickness issue. A solid 15 mm vs a hollow 15mm diameter
offers no advantage, RF wise. But in a 15mm diameter versus
a 3mm diameter comparison, the 15mm wins every time.

When I get that from a store that sells electronics (Circuit City seems famous for that), I ask the salesman a question I know he hasn't got a chance of answering, such as, "I'm looking for an AM-only radio that has a metal oxide silicon field effect transistor front-end."

You should see them run.

Consumer electronics manufacturers buy picture tubes and microwave-oven
transformers by the millions, and although they get quantity discounts,
that still doesn't make the parts inexpensive.

>So the charger (putting out 13.7V and 500mA) doesn't have enough juice,
>er current, to change this. So right now 500mA is being converted to
>heat.

I think there may be another interpretation possible.

What does your charger design look like? When it's in a "no load"
situation, and when you're measuring 13.7 volts, is there actually
enough load on the regulator IC's output to ensure proper regulation?
If I recall correctly, and LM317 requires a minimum of 10-20 mA of
load on its output to regulate correctly - without this, the output
voltage creeps up above what you'd expect. It's possible that under
light-to-moderate load (say, 100 mA) your regulator's output voltage
is dropping well below 13.7 and might need to be adjusted.

If you haven't already done this, try the following: stick a
reasonable resistive load on the charger (maybe 30 ohms 5 watts) so
that you're actually drawing an appreciable fraction of the charger's
normal output, and then readjust to 13.7. Also, use an ammeter to
make sure that the regulator is actually working correctly and is
truly delivering the amount of current you expect.

Oh... did you heatsink the regulator? The regulator might be limiting
the current flow (by dropping the output voltage) in order to protect
itself.

I don't think that 500 mA is being converted to heat. I think it's
actively charging the battery, which is probably at least somewhat
"run down". The time you'd see the power being dissipated as heat,
would be when the charger's output had risen up to 13.7 and the
battery was truly being "floated".

I suspect that you've looked at the situation shortly after connecting
the charger to the battery, while the charger was actively charging
the battery to overcome the previous amount of discharge. If you were
to leave the charger connected for a few hours or days, I believe
you'd see that the battery terminal voltage had risen to 13.7 volts,
and that the charger was delivering rather less than its maximum
amount of current. This would be the "battery is fully charged, and
is now being floated" state.

As an example: I have a 45-amp-hour glassmat battery, hooked to a
well-regulated charger (13.5 volts) which is powered from a 450 mA
solar panel. If I hook up the battery after a period of moderate use,
what I see is:

- Before hookup, the battery voltage is somewhere down around 12.3 volts.

- Upon hookup, the charger begins drawing maximum current from the solar panel. The battery voltage jumps up to around 12.6 volts. The charger turns on its "I am not limiting the voltage, as the load is drawing more than my input can supply" light. [If I use a 3-amp bench supply in place of the solar panel, the battery draws the full 3 amps at least briefly.]

- Gradually, over a period of an hour or more, the battery voltage rises upwards, and the current being drawn from the panel slowly decreases.

- After a few hours, the battery voltage rises to 13.5. The charger switches into "voltage regulation" mode.

- The current continues to drop off, flattening out to a few tens of mA after a while and remaining there.

I believe that if you monitor your charger and battery for a period of time, you will see a very similar pattern of behavior.

>This begs the question, what then is the point in regulating the charge >voltage to 13.3V (or 14.2V at freezing temperatures)? Wouldn't a >charger regulated at say 12.9V do just as well at keeping a full charge?

If I recall correctly: the reason for using a slightly higher voltage has to do with the way that electrical charge is distributed in a battery. My recollection is that the charge consists (conceptually) of two parts... a fairly evenly-distributed charge in the plates, and a "surface charge" on the surfaces of the plates / crystals which is present during charging.

The distributed charge is what gives you the 12.7 volts... it's the "steady state" charge within the battery. When you start driving more current into the battery, the "surface charge" appears (on the surfaces of the lead sulphide plates and crystals) as the electrochemical reactions begin to occur. If you stop driving current in, the surface charge decays away over a period of a few minutes or hours (or, quite rapidly if you start drawing current from the battery) and the battery terminal voltage drops back to 12.7 (or whatever its steady state voltage is).

The surface charge creates an additional voltage, which the charger must overcome in order to force current into the battery. If you try to use a 12.9-volt charging circuit, you won't get very much additional power pushed into the battery before the surface charge rises to 0.2 volts, the battery terminal voltage rises to 12.9 volts, and the battery stops charging. If the battery had been somewhat depleted (say, it was down to 12.3 volts), the surface charge will still jump up fairly quickly and cut down the charging rate, and it'll take a long time to "top up" the battery to full charge.

The 13.7-volt setting is, to some extent, a compromise. It's high enough to allow a battery to be trickle-charged up to full in a reasonable amount of time (it's high enough to overcome quite a bit of surface-charge backpressure), but it's not high enough to cause a fully-charged battery to begin electrolyzing the water out of its cells.

>This comes full circle on my original thread postulation. There is NO
>point in regulating the voltage, just connect a properly sized wall wart
>and you're done. The proof is right here.

The battery makers say you're in error - or, at least, oversimplifying, and taking risks with your battery. Lots of peoples' experience says likewise. Go ahead if you wish.

In certain very specific special cases, what you propose _may_ be safe. These would be the cases where the wall wart's maximum output current does not exceed the sum of [1] the static load on the battery, and [2] the amount of self-discharge current and loss-by-heating which would limit the battery's terminal voltage to no higher than about 13.7 volts. Because the self-discharge, and battery cell voltages are somewhat temperature-sensitive, I think you'd find that no single wall-wart would produce optimum results with a single battery under all circumstances.

In the more general case, one of two things is very likely to be true:

- The wall wart is smaller than ideal, and isn't capable of delivering enough current to pull the battery up to 13.7 volts in "steady state" operation. The battery will probably charge, but more slowly than would otherwise be the case.

- The wall wart is larger than ideal, and it pulls the battery up to well above the optimal float voltage. The battery begins gassing, and its life is shortened.

That's why a properly-regulated float-charging circuit is very desireable. It allows for a rapid recharge if the battery is run down (because you can use a nice, hefty DC supply) but ensures a stable floating voltage once the battery reaches steady state. And, a single such circuit can be used with a wide range of battery capacities - you don't need to carefully hand-select a wall wart to match each specific battery.

If you want to use separate antennas, why not bypass the built in
switching and use two antenna connectors. No losses, no problems with
switching times, either.

Which varactors are you referring to ?

Looking at the specifications for the BB212, which is a common AM
varactor on this side of the Pond, the relative capacitance error
between the two sections at 0.5 V is less than 3.5 %. However, the
limits for the absolute capacitance at 0.5 V is 500 - 620 pF.

>The tempco of those varactors is very low. Probably better than
>any inductor you are going to resonate it with. In the low
>100's of PPM.

BB212: 500 ppm/C at 0.5 V, 150 ppm/C at 10 V

> > To get such huge capacitance, the control voltage must be quite low.
>
>No it's not. The tuning voltage range is at least 10 volts and often
>higher. At least as high as the breakdown voltage of the gate
>oxide in a MOSFET.

The maximum tuning voltage is not the issue, the problem is at the low
control voltage area (maximum capacitance) in which the tuning voltage
to get the maximum capacitance can be as low as 0.5 V, which might be
less than the peak-to-peak voltage coming from the antenna.

>> varactor capacitance, thus, you would have to use two pairs of back to

The Toko web page for varactors seems to be under construction. Do you
have the type number for this kind of beast ? This would be really
nice for some LF experiments, if the specifications are really that
good.

Find out the specs on the candidate resistor(s). Resistors have a maxium current and voltage rating. Even for short durations, exceeding the maximum voltage could pose a problem for you. I always opt for conservative ratings...

Brian, probably NOT for a single 7 millisecond event...unless it is one
of the less-than-quarter-Watt SMDs. Using quarter-Watt carbon
compositions (cost about 5 cents), it is very easy to prove or
disprove on the bench with a few items from the junk box.

Conventional fuses CAN be a danger in "normal" applications if
mounted horizontally. I've come across three situations where
horizontally-mounted fuses rated greater than 0.5 Amperes did
NOT fully melt-and-separate the fusible link inside. In each case
there was sufficient voltage across the gap to arc over and continue
current flow. Mounting the fuse vertically insures that a melted
fusible link separate enough for HV B+ not to arc over.

The first such incident involved the plate supply for an AN/TRC-1
VHF transmitter (FM, 70 to 100 MHz, 829 in the PA) which had
(apparently, from post-mortem by in-the-know others of more
experience than I in 1954) a problem in its plate supply transformer.
The front-panel mounted fuse (horizontal) did not fully seprate its
fusible link, the short continued, the plate supply transformer
kept heating up and eventually boiled out some of the now-melted
potting compound. Potting goo spread over some of the internal
tube multiplier stages' wiring, then cooled down to encapsulate
all that wiring. Compound had to be melted with an iron, then
picked out, little gob by little gob. Some of the carbon composition
resistors lost their color bands, those having to be repainted to
restore the coding. [TM had photos of the wiring, resistors did not
have to be removed to check values] Some gas must have been
generated inside the transformer can since it sheared off two of
the 8-32 mounting screws and bent the tough aluminum chassis
slightly. Took several weeks of one person on each shift having
to play with goo removal.

In 1959 in the Electronic Warfare Lab at Ramo-Wooldridge, one of
my tasks was the measurement of Traveling Wave Tubes (S-band)

as 5-octave output mixers. About 2 KV (?) of supply voltage. The TWTs of that time would occasionally arc over inside. A series fuse was in the B+ line but encased in a plexiglass box. On a arc-over the fuse literally exploded...the reason for the box full enclosure. Way too much voltage for that 3AG fuse type but nothing else was available then to protect the supply, no quick crowbar circuits or other things semiconductor for protection.

The last incident was an old fuse-in-the-AC-plug that seemed to be popular in the 60s to 70s (but seldom used now). Fuses were horizontal when the plug was inserted into a wall socket. Friend's house damn near caught on fire before a mains circuit breaker kicked out...but not before the plastic plug had melted enough to expose the AC mains wires. The fuses just didn't separate their links enough physically once the links melted...arc-over continued with resulting hotness and things. We slightly modified a ground-fault protector (new product for the mid-1970s) to trip-out on over-current and that worked okay before we fixed the piece of test equipment that caused the over-current on the AC. Those 3AG fuses were rated for 250 V service, should have worked. Didn't.

You have a couple of potential problems with using an unregulated charger to maintain or charge a lead-acid battery. The first problem is that if the battery attempts to draw more current than the unregulated supply can handle you may overhead the transformer or other components in the supply. If on the other hand, the supply can supply more current than the maximum bulk charge rating of the battery then you may overheat and damage the battery if it is connected to the supply when it is not fully charged. The third problem results if the supply can output a voltage higher than 13.8 volts and can also supply the necessary charging current. The battery voltage will eventually climb to the supply voltage (above 13.8 volts), continue to draw charging current and boil the water out of the cells damaging the battery.

To be safe, you really need to regulate the voltage at 13.8V maximum AND limit the current to protect the battery and the charger. If you also want to get a fast charge on a discharged battery then you need a multi-state charger that will apply a higher voltage (about 14.5 V) at a limited current until the battery is almost fully charged and then switch to 13.8 V to top it off and maintain a "float" charge.

I expect your battery did not reach the no-load supply voltage because the supply was not capable of producing that voltage at the trickle current needed by the battery.

Fuck a Duck , Bruce,
this is becoming increasingly metaphysical - the mental effort you
(and everyone else) is putting into debating a car battery is
ludicrous. Let me make a few points.

1. If the battery is more than 4 years old its probably stuffed or
close to it. Sad but true.

2. Go and buy a hygrometer (they are about $3 - people used them
before digital multimeters were invented) - have a look at the SG in
the cells. If its green,
its OK. Check all cells, if 1 or 2 are very different SG then its
stuffed.

3. Do a load test on the thing, turn on all the lights and see how
much the voltage drops. Leave them on for 0.5 hour, if it drops much

below 12v then its stuffed.

How much does a new battery cost anyway?.....

Hi all,
overheating should not be neglected. In my professional life I encountered a device made by a famous company, which had a 7805 on a heatsink, a processor and several customer chips inside a tightly closed plastic box. All was O.K. at power-up. I was called for service after two days. The device was hot and really did not work. I let it cool down and all was O.K. again - for next two days. I was forced to remove the top cover of the box forever. The device has been working for several years now.
Proper cooling seems to be a must.

Agreed - the answer lies on the bench, not here on the Internet.

Take a candidate resistor, measure its cold resistance accurately, and then 'flash' it at 50W DC or 50/60Hz by brushing wires together. Repeat this several times, and monitor the cold resistance for signs of change or burn-up. That should be a pretty good accelerated life test for the intended application. Finally - and carefully - see what happens with a longer overload.

I once tested a 2W metal-oxide resistor at 10x rated dissipation, to see how much the resistance might change. The coating burned off and the resistive element glowed bright red, but even after about a minute it showed no sign of burning out. When it had cooled down, the resistor looked a mess but its resistance was still with a few percent of the original value.

So Len is right - you couldn't rely on all types of resistor to act as a fuse if overloaded for longer than the intended few milliseconds. Indeed, the types of resistors you'd be most likely to choose to meet the original requirement (handle 50W for 7 ms) would be the least likely to burn out quickly on a longer overload.

3839. WWII Spy or Clandestine Radio Building Contest

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-11-28 15:33:10 UTC
From: wa4uso@aol.com
Message-ID: <20031128103310.12107.00000782@mb-m26.aol.com>
Source record: 30655

The Louisville Kentucky Homebrewers building group is sponsoring a "Retro Building Project" for the late Jan. of 2004 meeting. The club members thought it might be a FUN idea to sponsor a WWII spy radio building contest. We have all built regens, reflexs, supers, and TRFs sets, but not a period clandestine spy radio. Open to all, the contest is designed to promote (hands on radio) building fun. The sets must be built from parts that were available before 1944, be able to receive 49meters shortwave broadcast and be hidden in plan sight. For more details email WA4USO@aol.com. Too True.

I've been a hardware/software designer for many years, don't rely on bench tests.

Go by the manufacture specs (unless it's a one off jobby for yourself) - least you have something to fall back on then.

Bare in mind, if any component gets pretty hot, in time the pcb will become charcoal in the components immediate vicinity - unless heat sinking measures are taken.

Message-ID: <8WvndwE4g3x$Ew7Q@langwang.demon.co.uk>
Source record: 30661

Has anyone home brewed a UV exposure box for making PC boards ?
I've got a couple of 8w UV tubes & a 0-30min timer and looking at
pictures of commercial designs I think all I have to do is:

1. Mount the tubes & timer in a light proof box.
2. Fix a sheet of glass 1-2" above them to act as a flat mount for the
photo sensitised PC board & photo master.
3. Fix a mask to the glass, blanking off all but a working area directly
above the UV tubes.
4. Make a lid for the box & fit a foam pad inside it that'll press the
PC board and master firmly down onto the sheet of glass thus stopping
those sneaky photons from getting round the corners of the PC master.

Is it as simple as this or am I missing something blindingly
obvious ?? Is 1-2" a suitable spacing between the tubes & glass plate &
will normal, thin, glass sheet be suitable ??

> voltage than the float voltage. That is normal. So it is
> possible that your charger is working properly and the battery
> is being held at full charge.
==========

The battery was fully charged when the float charging was started. The battery is almost new. The float voltage measured 12.7V with the charger connected. And the regulator is heat-sinked.

Someone outside of this thread who is more knowledgeable in this matter than I told me the following.

A float voltage of 13.3V is required to maintain a fully charged state (at room temperature). At lower voltages the battery loses charge, regardless of the output of the charger. So if the charger doesn't have enough current to keep it at 13.3V, as is the case here, then charge will be lost. If this is true then I should see a lower float voltage in the near future.

It's also become clear that regulating the voltage of an under-sized charger is pointless, because the battery never reaches a high voltage anyway.

Bob's point about overloading the charger is certainly valid. But right now it's only pulling a tiny current because the voltage differential is so small.

One conclusion can be drawn from all of this. The charger I built is inadequate for long-term care. And the wall wart chargers that are sold

for float charging are not suitable for long-term charging if they can't keep the battery at 13.3V. I'm guessing you need at least 2 Amps to do this. However an under-sized wall wart can certainly reduce the rate of discharge by compensating for external loads.

So what my home-brew charger is doing is just compensating for external loads and not adding to the battery charge in any way.

A lead-acid battery is not damaged until it falls below 12.0V. How long does it take a healthy battery to self-discharge to 12.0V? This might take a year. I don't have a feel for this at lower temperatures.

My charger will probably get the battery thru the winter, and certainly if I start the car every six weeks or so. So I think I'll just leave it at that. Thanks all for your help.

On another battery front, the gel cell in my computer UPS died of old age. Rather than replacing the battery I reconnected the UPS to a 32Ah gel cell which I keep around for emergency preparedness. This kills two birds with one stone, it keeps the big battery charged and also gives the UPS a whole lot of capacity. Now that I think about it, an old UPS might make a dynamite car battery float charger.

3845. Icom PS35 Problem.

Source record: 30660

Recently had an Internal PSU fail on an Icom 970. Fault was traced to a resistor going short due to some adhesive used at manufacturing becoming conductive with age? anyway resistor replaced gunk cleaned away. While repairing it was noticed the circuit has an optical switch in the start up circuit. This lost a leg when the short took place and despite repair it appears not too work.
Havent tried Icom as they seem to be quite useless, order replacement VFO assembly and received notch filter switch!

The device is a small black encapsulated unit, looks like a 4 legged black capacitor! It is Neon rather than LED according to the circuit diagram. Cant seem to find anything on it at all on the net. Appears to have been made by a company called Stuaw Kigai.

Anybody got any suggestions :)?

Basically, you are right, it is relatively simple.

Some standard glass will not pass certain bands of UV. Test first (put
a sliver of the glass partially over some sensitized material for a
standard exposure time and note any difference.)

You may not need the glass if the mask adheres well to the substrate.

You want enough spacing to get reasonably even coverage, but too much
will increase exposure time. Consistency is more important, so you can
develop a standard timing for the unit.

Consider mounting the lights to face down, as a safety precaution.
Also, you might add a microswitch and relay to prevent your box from
lighting up with the cover open. This would be a lot worse for your
eyes than a photocopier.

Happy trails,

To find the answer to the original question, "Can a 1W resistor handle 50W for 7msec?" the only sensible way is to check the manufacturers' data for a range of different types of resistor. I agree totally with that.

But the topic then moved on. The next question was: "If there is a fault leading to the 50W power input becoming continuous, will a 1W resistor act like a fuse?" This leads to the equally important question: "And if it doesn't, what will happen instead?"

The manufacturer's data won't completely answer those questions. It may specify the time to failure; but it won't tell you *how* the component fails, and what the safety implications might be. That's something you have to find out for yourself - rather carefully - on the bench.

If it's a 1W metal oxide resistor, the answer will probably be that it's a very poor fuse... but a very good fire-lighter.

I just picked up a couple of the float chargers from Harbor Freight.
They measure 13.55 no load. 13.55 at 130 ma, 13.4 at 175 ma, 12.9 at
230 ma, 12.8 at 250 ma.

Looks like they will only supply about 175 ma max and still be above 13.4 volts. At over 500 ma they will shut down and won't restart until the load is removed completely.

One problem I see with them is that they draw 36 ma from the battery if they are hooked up to the battery (at 12.9 battery volts) but not plugged into the wall. If you loose AC power that will quickly kill the battery!

They measure 3.6k both ways when you check the resistance but when hooked to the battery they cause much more draw than 3.6 ma.

These are the ones with the curly cords. Are these internally adjustable ?

I wonder if there is enough range to add a series diode?

Thanks
Gary K4FMX

3851. 4 foot vertical for 1.6mhz 100milliwatt tx?

Newsgroup: rec.radio.amateur.homebrew

I do sound work at horse shows, and would like to provide my audio source to vehicles parked at the show. I have a real nice 100 milliwatt input 1.6mhz transmitter which shows about 60 milliwatts of output at 50 ohms.

I would like to build a transmitting antenna that would be 4 feet in length and having the 3/8 24 thread at the bottom so I can fasten it into my hamstick mag mount base.

I am thinking a 1 inch diameter wooden dowel 4 feet long, and wrapped evenly from bottom to top with perhaps #22 wire.

Any idea how much wire it would take to begin to act like a 50 ohm impedance at the base? Would you solenoid wind it bottom to top, or would it work better with maybe a 4 inch high multilayered coil at the bottom and 3.5 foot steel whip antenna.

I am not out to piss off the FCC, and with a mere 60 milliwatts of output power at 50 ohms, I don't think anyone beyond 300 yards will even here it. I do however want to be clearly heard on an A.M. car radio anywhere on the show grounds. There are no local stations on 1600khz, or even anywhere near it, and since these shows are only in the daytime, I won't be competing with skywave, or 50kw clear channels.

>
>I'm thinking of taking regular audio, digitally processing it into >single-sideband using a
>soundcard, and then digitizing that to 8-bits.
>

Base audio has no sidebands, it is monoband so to speak. It does not become sideband until you modulate a carrier, remove the carrier, and possibly also remove one sideband. Even if you simulate this process in a sound card, which can be done, and you produce the 'garbly' sound, you still have 'audio' which when impressed upon your transmit carrier will still create normal double sideband modulation. The only way to get the result you are looking for would either to be taking your digitally generated single sideband and run it through a doubly balanced mixer with your intended carrier frequency, or perhaps digitally mixing your digital sound source with a digital representation of a sinewave who's repetition rate is the same as your intended carrier frequency. Your digital power output idea is a good one however.

You are very correct is saying they are hanging up the parts business.
Radio Crap is an investor owned company, and they want to sell big profit
margin items, and more expensive items. How many resistors must they sell
to equal the money made on one very overpriced printer cartridge?

It has always been common knowledge that RadioShit NEVER wanted technically
knowledgable persons as employees!! They wanted SALESPERSONS employed as
salespersons. Technical persons would slow down sales by dedicating way to
much time to somebody trying to find a good replacement for a 2N404 used in
a 'radio experimenter' magazine 'build your own metronome' article from 1954.

I saw a guy with a 470mfd @ 16vdc cap required, and he asked the crappyshack
bozo if the rodeolack 470mfd @ 25vdc replacement part would work. Mister RS
Suit-n-Tie said "Oh no, it has far to much voltage, and would blow your circuit
up". If I told you I wanted to cause Mr.RS bodily harm for being so stupid
in his field, would you have helped me?

Radio Shack, a collection of techno-lackies, who all own 2.4ghz computers in their homes, and would not know a 12AX7 from a Dean's Peacocks condom.

Sadly, I have resorted to buying up everything I think I may ever want or need for the next 15 years of my experimenter life at local hamfests. Not only are experimenter parts that are big enough to see becoming harder to find, but people who know what to do with the parts are about as rare as monkeypox.

Now I will go back to my cave, and remember all the cool things I showed my blue shirts how to build using just the stuff we found while pillaging the dumpsters on the Navy base. Damn, we had some cool stuff!

Just call me Chief.

I made my own from three pieces of MDF, some wood strips and a sheet of glass. It's got the tubes etc. in the MDF base and two upright pieces of MDF with two strips of wood acting as a shelf for the glass, about 9" above the tubes, to give a bit of collimation. Glass is quite transparent to the long-wave UV used for PCBs. I just put a book on top of the board to press it down when exposing. I keep meaning to make a proper lid with a foam pressure pad, but can't really see the point as I don't use it much. It's some distance away, so I'm not bothered about getting sunburnt. 8-)

At 1.6 MHz at 4 foot long helical would be very low impedance - probably around 1 ohm or so at resonance. You would have to feed it against ground - ground losses would be 30-50 ohms, depending on your grounding mechanism. So the antenna might be a good match but radiation efficiency would be only 1-2 % as most of the power will be lost in ground resistance.

not true. consider that you are whistling a pure tone of 1KHz into an
SSB transmitter's input. If the SSB transmitter was tuned to 7.000MHz,
you would get just a carrier at 7.001MHz. Thus, a single tone SSB
signal is virtually indistinguishable from just a carrier.

now consider that the human voice is expressed as a number of
simultaneous pure tones superimposed over each other (easily obtained
by converting the time domain signal into frequeny domain).
Now imagine that for each of the tones, you have a separate
transmittter offsetted from the carrier by a frequency obtained by
frequency analysis and also with equivalent amplitude. this is in
effect, the SSB signal.

to rephrase, we need to modulate a carrier and then remove it because
that is seemingly the easiest way to generate SSB (but not a necessary
way).

> Even if you simulate this process in a sound card, which
> can be done, and you produce the 'garbly' sound, you still have 'audio' which
> when impressed upon your transmit carrier will still create normal double
> sideband modulation. The only way to get the result you are looking for would

there is an entirely different approach, we are advocating that we
split the signal into a number of component audio frequencies and
essentially run a carrier that is the equivalent of each of those
frequencies.

From the above example of a single tone, lets expand this to a two
tone ssb exciter. Lets imagine that such a signal can be represented
by two carriers that have relative amplitudes of the two tones and are
shifted from an imaginary carrier by amounts equivalent to their tone
frequencies.

a frequency modulated signal generates sidebands according to a bessel
function. Thus a correctly modulated FM signal will also result in two
tones being generated at two frequencies. In order to control multiple
sidebands, an envelop shaping will have to be applied to the FM
signal. The frequency modulation and the amplitude modulation can be
easily computed digitally.

What is really difficult is to accurately frequency modulate the carrier. One way is to directly generate the carrier digitally using DDS. I am not aware of any amateur effort in trying this method out. I seem to have vaguely read about it in either EMRFD or the new ARRL Handbook.

1) 60 mW RF out for 100 mW DC input sounds like suspiciously high
efficiency.

2) To a VERY rough approximation, I'd aim to put a quarter-wave (at 1600
kHz) of wire on the dowel. That's almost 200 meters / 660 feet. I doubt
that you can fit that much on the dowel. In any case a tophat on the dowel
will partially compensate for too little wire. Even something a foot or two
in diameter might help a little.An example: a broadcast station near 1600
kHz has a tower only 67 degrees tall (less than 90 degrees / 1/4-th wave).
At the top they stick 4 or 6 or 8 10-ft-long rods straight out to the sides.
They claim this top-hat is the equivalent of 10 degrees more tower height,
bringing them up to an equivalent of 77 degrees. With this they claim to
meet the FCC's required minimum antenna radiation efficiency for their class
of station. Top-hats like this are pretty common for AM stations. Sometime
they use the top few feet of the guy wires.

3) Putting the loading coil at the bottom of the antenna is the worst
possible choice. It's the current flowing in the antenna that radiates, and
the current is highest at the feedpoint and zero at the tip, for
quarter-wave and shorter antennas. The high current points would all be
hidden in the loading coil and only the high-voltage/low-current part would

be "visible". Look at the short CB antennas. They will be have most of the turns of wire near the tip.

4) Your mag mount won't have enough capacitance to the vehicle to be a really good connection at 1600 kHz if you manage to make the antenna impedance low, like 50 ohms.

5) In any case, the impedance looking into the base of any antenna _I_ think you can fit in 4-ft length will be much higher than 50 ohms. You should build a matching network. The less wire you can fit on the antenna rod, the higher the input impedance. Look in the ARRL Antenna Book for networks for feeding short antennas on the 160 meter ham band. The coil in a matching network should be wound with rather hefty wire for low loss.

That'd be 100mW *DC* in for 60mW *RF* out! Nothing wrong with that.

You need one of Reg Edwards' utilities to work this out for you. He's
written a number of small programs for the PC that handle exactly this
kind of problem and they're available for free download. I can't
recall the URL off hand but just Google for "Reg Edwards" on the
newsgroup sci.electronics.design and that'll bring it up.

I rarely mention it, but I have some parts listed on my website. The
link is above, in the "Organization" line.

> Now I will go back to my cave, and remember all the cool things I showed

I nearly got myself court marshaled at Ft Greely, Ak. for grabbing
junk TV sets on their way to the base landfill to keep the base's AFRTS
TV and Radio stations on the air.

You know the drill. Zero downtime, almost everything is depot level,
or requires a traveling engineer to fly from Sacramento to patch it, and
the money comes out of your budget. I was tired of being off, more than
on the air, the poor signal Quality, and the constant equipment
failures, so I rebuilt the entire TV station and half the radio station
while I was there. I even used parts from a TV set to replace the tuner
in the old Off Air Demodulator. No way I was going to wait two years for
RCA to dig up the part and spend over $2000 for a 29 dollar
Sarkes-Tarzan TV tuner.

The best range has been reported using a Part 15 antenna mounted high and
in the clear on a metal structure--20 feet of water pipe will do. Do a web
search
for "part 15 am antenna" and you will get a lot of hits.

Now, the problem with part 15 is the interpretation. Some field engineers
will
argue that the loading inductor wire length should be counted against
against
the three meter total length permitted for the antenna and "ground lead".
The
six foot "ground lead" is also subject to interpretation... If you look at
some
of the better commercial units, they use a shielded loading coil, with a
110
inch or so whip.

I need some of this stuff for antenna assembly. Anyone know where to get it?

For those who don't know what it is, it's a paste you get in a little can or tube that you smear on mating metals to avoid having them stick together after exposure to the elements. It's also used for soldering irons to make replacing tips easier.

I think it's molybdenum disulfide.

Bob:

http://bosunsupplies.com carries it (well,a t least one version thereof).
Bosun Supply is an excellent source for all sorts of stuff useful in ham
radio. Besides, when I order from them, I can pretend I own a 40 ft sloop.

Any electrical parts place sells it. It is commonly known as Penetrox
or inhibitor paste. It is primarily used for aluminum wire contact with
terminal strips.

Two electronics stores and Home Depot didn't have it.

I finally found some at my auto parts store. I was told that Ham Radio Outlet had it for $8 but I only paid $3 for a decent sized tube of the stuff.

Thanks for your help, guys.

The stuff I use is from Lawson...its simular to CopperCoat, but its 80% copper and works great. it takes very little...*maybe* a tablespoon full to do a 4 element tribander, but after 4 or 5 years in a really bad salt environment(Treasure Island in San Francisco bay), everything that had been put together with this stuff came right apart when the screws were taken out...anything that didn't get the antiseize was junk.
The stuff is expensive but worth every penny.

Automotive anti-seize is not the same as electrical.
Different purpose.
The automotive is to keep steel bolts from binding in aluminum, magnesium,
etc.
The electrical is to keep the coated materials from oxidizing while at the
same time ensuring good electrical contact.

Hi

planning a power supply for NEC 36284 150W 2m linear amplifier with
2SC3286, see http://home.online.no/~la8ak/images/nec36284c.gif

It is only a simple psu, but using a 24VAC transformer
[http://home.online.no/~la8ak/images/4ua3.gif)

Wonder what size capacitors I should use to keep ripple minimum above
+24V?

Hi Bob ... I applied Permatex anti-seize to the bolts on my tower and the boom-mast-rotor hardware. The whole works came apart smoothly after being up for 20 plus years. The material I used between the Al junctions on the TH-6 was supplied by Hy-Gain in a little metal pill box. Likewise the stuff worked great. SS hardware used on the antenna.

Ripple voltage across smoothing capacitors can be calculated from the amount by which they discharge, at the DC load current, during the time of a half-cycle of the power supply frequency.

For half-wave rectification, ie., a single diode plus capacitor, the capacitors are charged up once per cycle and the capacitor discharges into the DC load during the period of a whole AC cycle.

Heikki - See QST for 8/78, 12/78 and 11/80 for answers.
If I have room, I put a mini trimmer cap in series with each xtal
to tune all the xtals to the exact same frequency.
This helps the bandwidth and reduces the insertion loss.

Message-ID: <8891d193.0311300316.8ea264c@posting.google.com>
Source record: 30599

hello,
i am a student and we got a hf task for a lab project. we have to
built a low pass filter (-3dB @ 500MHz, 3th order) in microstrip,
coupled lines and interdigital. the first two we have to build and
measure, the 3th one is to calculate only. i know the last two filters
are band pass, but we should design something with highest brakepoint
at 500MHz.

now my question:
we managed to calculate the microstrip filter so that one is done and
simulated. what botters us is that we didn't get ANY sort of a course
(we have to find anything on our own) and we have no clue about the
coupled lines and even less about the interdigital filter.
there is very very little useful information to find on the web so
please can someone help me here by giving some basic
methodology/formulas for coulpled lines or interdigital filters. maybe
someone has a few pdf's or other info on his harddisk he/she could
send me?

thanks in advance
lenx

==========
Suggest you consider using an optocoupler with a suitable input and output
circuit added.

Not knowing the voltage levels the failed component operates at and whether
it is in an AC or DC environment,the opto-coupler's input circuit could be
tailored with a resistive network (possibly with an added diode in case of
an AC circuit) and the output circuit with a HV transistor if necessary.

May be for a different purpose but have used it on antennas for along time and have never had any problems with it. Seems to conduct just fine and will certainly let things come apart easy. Last use was on a TH6DXX, no ill side effects, still up and working without any problems. Antenna analyzer shows all is well.

=====
As a rule of thumb not less than 2000 microFarad per ampere
Hence for a 20 Amperes supply a total of 40KmicroFarad or more.

In the UK a very good stuff for outer metal protection is Finigan Waxoyl,
available from many autoparts - and hardware shops.
Living in a windswept area near seawater ,hence with a lot of salt spray ,I
use it on all bolts and nuts and galvanised metal clamps etc.
Of course it is NOT suitable to make galvanic contact between (dissimilar)
metal parts.

Yes, I have used the NeverSeez conductive grease, sold for automotive
repairs, on things like car battery terminals, to resist corrosion and
enhance conductivity. It does fine there.

As long as conductivity is good, and there is no capacitance created,
it should be fine.

There are two varieties. One is a mix of graphite and moly in a syrupy solvent. One is a mix of copper dust and moly in a pasty solvent. Either one works well and we notice not a whit of difference in the conduction properties. In the aircraft industry, we use them rather interchangeably to coat the threads (lightly) on spark plugs so they won't pull out the helicoils in the heads when we go to change them annually, on manifold and muffler bolts so we don't have to drill them out when it comes time to work on them, and on any other thread that is likely to become corroded into place.

If necessary, you can go to an aviation supply house (Chief Aircraft, Grants Pass OR; Aircraft Spruce, Fullerton) and buy as much as you need by mail order. In a really well-stocked automotive supply house you can buy it by the dribble bottle, pint, or quart.

What books does your course use? Pozar's "Microwave Electronics" book (or perhaps "Microwave and RF Design of Wireless Systems" -- there's some overlap between the two with the later typically being less theoretical and more applications oriented) is the one that immediately comes to mind for your problem.

Why are you only looking on the web? Does your school
not have a library?

There are zillions of papers on the subject out there.
I'd start with either RF Design or IEEE Microwave Theory
and Techniques.

This is definitely a "me too."

Waxoyl is excellent stuff - a blend of wax and oil (surprise) plus corrosion inhibitors that really work. I recently pulled out a rotating pipe mast that had been sitting in a ground socket full of Waxoyl. 10 years of condensation had turned it into more like an oil/wax/water emulsion, but the bare steel came out looking like new.

In more normal use on nuts and bolts, the oil dries out and the wax coating hardens, so it also acts as a pretty good thread-lock.

Don't know if Waxoyl is available outside of Britain... but if it isn't, it should be!

Work it out for sure, using Duncan Munro's PSU Designer program. Follow
the link from the 'In Practice' pages:

While cleaning thru the antique electronic mess in my basement today I came across two National Radio knobs. One is the usual National grey about 5/8 in diameter and 5/8 in high with a small white spot as a indicator. The other one is new in package marked HRS-5 "Black knob". Thought I'd check first if someone can use these before I throw them away. Larry

He's probably looking because the web tends to be more efficient in its searches than any library (i.e., Google searches the contents of web pages themselves, whereas libraries are only able to search via titles or sometimes summaries) and also because the web tends to be have its eye a little more bent towards practical applications rather than strictly theoretical concerns (something that libraries are filled with!). Of course, I'd never suggest a library isn't a wonderful resource as well, just giving you some insight from someone who's spent plenty of time in both.

> There are zillions of papers on the subject out there.

Yes, but unless he uncovers one that's specifically meant to be a review of well-known subjects or tutorial in nature (such papers do of course exist, but they're few and far between given that most professional journals are aimed at publishing new research), he'll be wasting his time since it's clear he needs some pretty introductory material at this point.

Sorry if this sounds unkind, it's just that a lot of students I know have wasted tons of time trying to understand journal articles when what they really need is a good textbook.

I do like your suggestion to check out some of the trade magazines such as RF Design, however!

Visited my brother in Atlanta.

Dropped by Radio Shack Friday afternoon (after Thanksgiving) for some 75 ohm
CATV terminators (spare ports on cable splitter)

Did not have any, manager was in (big sales day and full staff in store).
He told me if it is not in the box .. they will not reorder..
and that RS was going to fade out of the parts business at stores because of
SLOW inventory turns
(think WalMart, Home Depot and sell only volume items). Ace Hardware down
street was doing good business in these specialty items that
these stores are now walking away from (and great service).

Greetings. I just picked up an Oyster model 4 handheld serial terminal at a surplus sale. It is about the size of an old TI calculator and appears to work. After much trial and error I got the baud rate set on it to communicate with my packet TNC. Does anyone have any documentation on this thing? I am specifically looking for the way to enter the setup mode. I dropped the company a line, but after two weeks still have not gotten a reply. I plan on using this for amateur radio as well as some work related projects. Thanks in advance. 73 de Bob W8IJG

I would also recommend Newark Electronics (think the URL is
www.newarkone.com). They have a catalog that is thicker and heavier
than the Manhattan phonebook! (And they will send you a copy for free!).
Newark has a $25 min order, but you will have no trouble filling this
(because they have so much stuff you will find to buy!). Newark drop
ships your order from their nearest (to you) warehouse, so shipping
charges are reasonable (though your order may come in several packages,
and I don't think you pay extra for that). And they take Visa,
Mastercard (and maybe even paypal!). Newark's catalog business is
almost as old as Allied's, but they are mostly a wholesale outlet (they
try and keep the retail side a secret?).

There is also Arrow Electronics and Schweber (If there is a local
Schweber, you can phone your retail order ahead, pay by credit card and
pick it up at the lobby window.) I've done business with all three of
these companies with no problems.

You must not be a ham.
Hams never (shudder) throw anything away.
Their widows do....

Thanks for the words-of-one-syllable-or-less explanation.
If the information isn't on the web, no search engine is
going to find it.

> > There are zillions of papers on the subject out there.

The ARRL and RSGB have published numerous books on
microwave stuff. Not only does the material tend to be
at a very practical nuts and bolts level, the references
tend to be pretty good. There are lots of others,
thugh the specialist journals like VHF Communications/
UKW-Berichte and DUBUS tend to be hard to come by.

What makes you think I don't know what being a student
is like? I'd hate to think I wasted such an obscene
amount of money on my B.Sc. and M.A.Sc. degrees. I
completed the latter in 2000, and the Internet was an
important tool. But it wasn't my *only* tool. Anybody
who thinks it is is either naive or stupid.

Some points:
1) The input to the regulator must be about 2 volts above the
regulated voltage level. So, if your regulator is set for
13.7, the DC input to the regulator must be about 15.7.
Under no load, what is the DC voltage at the input to the
regulator? What is it under full load?

2) A wall wart's output voltage will sag under load - the
heavier the load, the greater the sag. The ones that don't
sag have the regulator built in. How much current is being
drawn from the regulator when it is connected to the battery?
What is the wall wart voltage sag, no load to full load?

3) If as you mentioned the voltage differential is so small
that very little current is being drawn from the charger, then
there should not be a differential of 13.7 to 12.7, no load to
full load as measured at the charger terminals that clip
on to the battery. The problem is that the phrase "very little
current" is undefined. We need the actual numbers.

Bottom line - it sounds like your wall wart may be too wimpy
for this application. Also, it would be a good idea to
post the details of the circuit. For example, do you have
a diode in the output between the regulator and the battery?

If not, how do you protect the LM317, and how do you prevent
the battery from discharging through the charger?

In your reply you mentioned:
> It's also become clear that regulating the voltage of an under-sized
> charger is pointless, because the battery never reaches a high voltage
> anyway.

It's not the regulator that's pointless, it's using an
under-sized charger in the first place, and expecting it
to keep the battery at ~13.7. When you expect a charger
to keep a battery at ~13.7, regulation is required. When
you don't care what the battery voltage is, no regulation
is required. Of course, that's no charger at all - it could
allow the voltage to go anywhere, and it disagrees with what
battery manufacturers recommend - voltage regulation for
trickle charge.

Popular Electronics magazine, Nov 1962, had a broadcast band transmitter project: "RFD 100" (housed in a rural mailbox). The center loaded vertical antenna may suit your purpose. It is constructed with two 53 inch lengths of 1/2" copper pipe with a 8" diameter by 12" long loading coil wound with 88 turns of #20 wire between. Article has generous details on construction and tune-up.

First, could you answer a few questions to narrow the field a bit.

Are you primarily interested in building radios? Transmitter or receiver? Accessories? What frequency ranges? Tubes or solid state? Interfacing to computers or standalone projects? What level of experience do you have and what are you starting with?

Sounds like a lot to ask, yes, but it really does make a difference. If you go out and just start buying things, you can put several hundred or (if you go overboard) even a thousand dollars into parts without really being able to build much.

For most experimentation, a decent selection of resistors and capacitors is pretty essential, but the actual ranges of values of each is considerably different depending upon what type of projects you have in mind. Likewise, diodes, transistors and other semiconductors. There are some "standards" but it really depends upon what you are planning. These days, there are a lot of projects involving logic, and you can really spend a fortune restocking for logic projects if you don't know what you want yet...
When I started oh so many years ago, I began with a full assortment of halfway carbon composition resistors, along with a couple of capacitor assortments (disc and tubular). Now, most of the resistor values I have are quarter watt carbon film types, and the capacitor assortments comprise three or four different types and several voltage ranges. Diodes range from small signal types in germanium and silicon, along with the 4001-4004 1 amp general purpose types. For transistors, an assortment of common pap and nun devices (such as 2n2222a, 2n3906, 2n3906 and so on), plus a handful of various ICs and pampas that are used often.

Often, people that don't have a fairly well stocked "junk box" begin with kits or published magazine articles that are of particular interest, then go on from there, expanding upon the parts they purchase for each kit or published project as they go along. Whenever I make up an order for a particular repair job or project, I always add a few other things to the order to round out what I was missing the last time I had something I needed to do... It helps to reduce the average cost per part due to minimum order size or high shipping charges.

Of course, beyond just the parts will be some general equipment, such as a variable power supply or two, a decent DVM, and possibly an oscilloscope, depending upon what you are building... Don't forget to buy a good soldering station (the Welder WTCPN or other similar models come to mind), some solder wick and a good solder sucker. Having a quality, temperature controlled soldering station will make soldering so much more convenient you'll be able

to do a really good job with a lot less practice. Of course, a good quality small diameter flux cored solder is essential. Then there are hand tools like exact knives, wire strippers, diagonal cutters (dikes), needle nose pliers, tweezers, screwdrivers, nut drivers and the like. The list (seemingly) goes on and on.

Good luck!

>>planning a power supply for NEC 36284 150W 2m linear amplifier with
>>2SC3286, see http://home.online.no/~la8ak/images/nec36284c.gif

Is this really a 2m amplifier with a large number of striplines? I
guess that the amplifier would be quite bulky at such low frequencies.

Assuming 50 % efficiency, 150 W RF would require 300 W DC input power
or 12.5 A.

>> It is only a simple psu, but using a 24VAC transformer
>> [http://home.online.no/~la8ak/images/4ua3.gif)

The secondary peak voltage Vpeak will be about 1.4*24 V or about 34 V.

Since the rectifier voltage drop is at least 1 V at large currents and
there are two rectifiers in series, the voltage drop is at least 2 V,
so the peak capacitor voltage is less than 32 V.

>>
>> Wonder what size capacitors I should use to keep ripple minimum above
>> +24V?

As the lowest allowed voltage is 24 V, the capacitor voltage will drop
from 32 to 24 V (dV=8 V) between the half cycle peaks.

The hard part is to calculate when the rectifiers stop conducting
after the peak and when they start to conduct again in the next half
cycle.

The worst case capacitance could be calculated assuming that the
capacitor must deliver the current for the whole half cycle, thus 10ms
for 50 Hz full wave rectification. Since dV = I*t/C and rearranging C
= I*t/dV, thus the required capacitance would be C = 12.5 A*0.01 s / 8
V or 15.6 mF.

However, since the final capacitor voltage Vl is well below the
secondary peak voltage, the rectifiers start to conduct well before
the peak of the next half cycle. The conduction angle is given by
arcsin(Vl/Vpeak) so in this case arcsin(24 V/34 V) or arcsin(26V/34V)
= 50 degrees, if the rectifier voltage drop is included. 50 degrees is
more than 2 ms before the next peak.

Since the conducting after the previous peak occurred slightly after
the peak (due to the serial impedances in the transformer and
rectifiers), a good guess for the time when the rectifiers are not

conducting is 7,5 ms in this case.

Using this shorter storage time, the required capacitance can be recalculated as 11.7 mF or 11700 uF.

It should be noted that in this case the 8 V is the peak-to-peak ripple voltage and 24 V minimum output voltage during a cycle, which is quite appropriate if series pass regulation is used. Some design equations especially from the tube era talk about RMS ripple voltage and average DC voltage, which was more useful when a choke was used in the high voltage supply.

>=====
>As a rule of thumb not less than 2000 microFarad per ampere

That gives a voltage drop rate of 0.5 V/ms.

With discharge times from about 6 ms (60 Hz full wave) to 20 ms (50 Hz half wave) the voltage drop would be 3 .. 10 V.

If this is much or not, depends on the voltage levels used. A 3-4 V drop might be appropriate for a full wave 50/60 Hz system generating 12 Vdc, but for a 24 Vdc and higher systems a higher ripple can usually be tolerated, thus the capacitor can be reduced.

>Hence for a 20 Amperes supply a total of 40KmicroFarad or more.

Hopefully the amplifier will not consume 20 A (480 W), since the efficiency would be quite low :-).

the
> old FT243 or HC6U types.

Here's my one-valve CW transmitter, produces up to 10W on 80m and 8W on 40m:
http://www.hanssummers.com/radio/cwtx/index.htm. In this circuit I have
found that modern HC49 type crystals work perfectly well. Before building
it, I was warned that HC49 crystals are too small for valve circuits and
would fracture. Fortunately I decided to give it a go anyway, and have not
yet had a crystal fracture. Some have suggested that this may be due to the
DC blocking capacitor in series with the crystal (see my circuit diagram).

Quartzlab charge £7.50 per crystal (minimum order £10). A cheaper way is to
buy a bunch of standard value crystals and lower them by painting the
crystal surface with felt tip pen, see my page about it:
http://www.hanssummers.com/radio/penning/index.htm. In this way it would be
possible to build up a bank of crystals covering a segment of the band.
3.579 (TV colour burst) crystals are available almost anywhere extremely
cheaply, and I found it easy to lower it by 30KHz. 3.560 crystals are also
available, it's the 80m QRP calling frequency. See the links page on the QRP
website http://www.gqrp.com for some suppliers. Similarly 7.030 (Europe) /
7.040 (US) is the 40m QRP calling frequency, and they can be easily lowered
to anywhere down to 7.000.

My TX has 4 relay switched crystals: 3.558, 3.560, 7.010 and 7.030. All are
(or were originally) HC49. After 2 years and over 400 QSO's, no fracturing.

Really? Without knowing what your degrees were in, I'd say it's naive to assume the Internet _couldn't_ be your only research tool. Although it's still certainly quite uncommon, I'm sure I could find you some computer science/computer engineering students who have graduated in the past few years (maybe even in 2000 :-)) that never once visited a brick and mortar library throughout their program. I'd also predict this will become increasingly common in the next few decades as more and more publications end up in electronic libraries (sometimes _only_ in electronic libraries!).

What, simultaneously? That's gotta make for one whopper of a
headache. ;-)

Odd that you should mention antennas on one's head. I've seen a
couple of hams mount an SO239 through the top of a hard hat, glue
aluminum foil connected to the shield side on the inner surface, and
attach a 2m or 440 flexi-whip to the topside for use with their
handheld. It apparently works pretty well, but it's not something I
would choose to do.

Shiny side out, Anton?

I've also seen more than a few folks put a GPS antenna inside a hat
or cap, so that the only thing showing is the lead down to the GPS.

It takes _all_ kinds, as the saying runs.

Don't forget the battery powered AM tube radio built on a pith
helmet, with the tubes sticking out the top! ;-) I think it was Bill
Morris who posted a picture on news:alt.binaries.radio.pictures a couple
months back.

From: W3JDR <joe@roccis.com>
Message-ID: <qvPyb.20760$lF6.10973@nwrdny01.gnilink.net>
Source record: 30644

My little project ,which started out to be a software-controlled HF sweep set, has taken on a life of its own. Although I'm calling it an HF Scalar Network Analyzer, it is now much more. The unit supplies unregulated 12V and regulated 5V to the circuit under development. The software system now has an analog meter panel that measures the DC output voltages, the DC output current, and also the DC voltage measured by a set of plug-in test probes. I'm going to start calling it the "HF Test Bench". It's all built from inexpensive off-the-shelf sub-assemblies. The power comes from the software.

If you're interested in seeing what I'm doing, check out my web site at: http://mysite.verizon.net/jdrocci/.

You can download my latest demo software package and get a feeling for how exciting this project has become.

Think it is 110V after a resistor. Think its 300v before. The problem is it is contained in an area that is very small and surrounded by other components. Opted to strip the device and will try and find what exactly, has gone up in smoke! Maybe repair existing one. Would have hoped gareth or one of his cronnies would have given me their expert guidence, they always witter on about, but nope :(Oh well. Thanks to the two people that have emailed me. The guy with the 2.4Ghz units can you resend your email as it got deleted by mistake :(, before I got to reply. Bit over zealous with delete trying to get rid of SPAM!

In 'Amateur Radio Techniques' by Pat Hawker (RSGB publications)
there's a design called a 'titfer' for a hat antenna for 2m operation.

Hi

have some problems to find data for MMIC MSA0304,
only need to know the bias resistor for Vcc=9V and/or 12V, IP3 and
gain

need it for a general purpose noise source with MPS918 to cover
500-25000kHz band for selectivity tests. The reason for using this old
device is that I already got some douzens

what sort of narrow band noise evel could I expect in a 1kHz BW from
MPS918 emitter-base-junction noise source?

But ... but if you put it on your backpack, then it winds up looking
like one of the backpack GPSen from the Ashtech or Trimble catalog!
Where's the fun in _that_?

Now, if you mount one of the high-$, high-precision Trimble or Ashtech
GPS antennas, complete with planar choke-ring array, on or under your
hat, _that_ qualifies as well out on the tinfoil-hat axis. I wonder if
my Garmin 76 will talk to one of those, and where I can get one cheap.

The MSA-0304 is identical to the Mini-Circuits MAR-3 part.

Have a look at http://www.minicircuits.com/dg03-170.pdf

MAR-3SM
12.5dB@100MHz gain
+23.0dBm IP3
Operating current and voltage: 35mA 5.00V

[request hammers help]

Requesting help in gaining the release of a kidnapped United States Citizen who is being held in Romania and other locations against her will.

Information regarding this young lady can be found at:

http://www.PrincessOfRomania.com/

A rough outline has begun to be constructed of the past two years of her life with links that may help investigators generate leads to where she currently is being held so that more localized strategies can be initiated to secure her release:

http://www.PrincessOfRomania.com/princess_diaries.html

All help is appreciated. There is also a small banner that can be used to link to this site if you find it in your heart to place it somewhere on your websites:

http://forum.princessofromania.com/viewtopic.php?t=9

in the late seventies, i bought my first book on electronics. i bought it because it was cheap, it was cheap because it came from the erstwhile russia. it was a really excellent book called 'entertaining electronics'. i really rocked.

one of the more interesting stories was that of a man who went to his shrink saying that he was hearing voices in his head asking him to buy something or the other. after a while, he started reporting news, weather and sports! at this point, the shrink realised that this dude was actually able to hear radio broadcasts. they seem to be improving with age, literally.

an investigation releaved that he had a recent tooth-capping done. the tooth-cap was slightly oxidised and the nerve-end formed a cats whiskers which was direclty pumping AM broadcasts into his nervous system! i don't know if the story was interesting, but it compelled me to read the entire chapter on holes and electrons.

thanks to all for the reply.
my school has indeed a library where we had a look some time ago.
there's a whole rack full of books on RF design, but most of them that
cover stripline or microstrip are bulky things full of formulas we
don't need.
we're not really looking for such thing, we are looking for a way to
solve the problem with pencil and caculator, esprecially for the
interdigital filter cos we have no clue about that.

so far we started from a 3th order filter with lumped elements and
then converted it to a structure with kuroda elements.
now what we need to find out is how to calculate the dimensions of the
coupled line filter and the interdigital filter, given the kuroda
filter structure. we already managed to do this for the filter with
stubs (the most easy one probably :-)

tnx.
Tried check some noise generator descriptions, although I plan to use
e-b junction of MPS918 and found this good 25 years ago, but I
couldn't find any indication of the RF output level from different
types of sources.
Some noise bridge sources may have an amplifier because - to adjust to
null you need at least 40dB more signal than heard into the RX at zero

My purpose is checking selectivity to compare different boatanchor
receivers in different modes, and I need at least 1mV, so an MSA0304
or two doesn't seem to give sufficient gain...

QST has been known to have many good homebrew articles over the years.

Plus the other mags/newsletters mentioned above.

I bought the whole SPRAT collection at Dayton for like $15 a couple of years ago, so much homebrew in there you can't get it all done.

I just got in some of the SMT version of the D44H11 and D45H11 -- MJD44H11's from ON-Semi -- in a 369A-13 type case. While I created a chip outline in my CAD program to accomodate the new pad outlines, I am perplexed at how to actually heat-sink and mount them -- the devices on the AavidThermalloy web page would seem to require a cutout and pair of slots in the PCB AND a "heat spreader" so that the device rests flat with the board and that the Emitter and Base come into contact with the pads and align with the PCB.

Can anyone point me in the right direction for assembly? Looks like the usual suspects (Mouser) carry D-PAK heat sinks which would work, but I'd like a bit more information.

Would you care to explain that? Where does shortening the elements come into
it?

I'm not really looking for gain - these antennas are meant to be "cloud
warmers",
want to connect with ISS and whatever sats are reachable. There may even
be balloon "sats" in my future!
I'm way too broke right now for a high gain, multi yagi, steerable, beam
assembly.

Now here comes the complication...

Would I keep the bandwidth advantage if I use 3mm for the radials and 15mm
for the radiator? The reason being easy costruction - solder the rods into
the chassis mounting holes on the SO239. Putting some kind of flange and
"nipple" on the 15mm pipe to get it into the socket centre-pin seems to be
not insurmountable.

I suppose you could use one or two more MPS918s in an untuned
amplifier configuration before a MAR-3. You don't need gain
flatness, do you? The MAR-3 should give you a well-defined,
well-matched 50ohm output, since you have 'em you might try
using one.

Hi Group,

My wavetek sig gen covers 100KHz to 512 MHz and puts out about 10mW. I need a simple circuit to cover HF which will boost this up to 500mW. I would like to try out the signal generator as a low power CW transmitter.

I have a few CBs around that I could use the RF amp to get me on 10 meter but I am not sure of the drive level. I am not sure if this amp would work below 24 MHz without re-tuning.

Anyone have a simple wideband circuit that could cover 3.5 to 28 MHz?

I have built a noise source using a series of amplifier modules, similar to the MSA-0304.

It is essentually flat in frequency response up to several hundred MHz, which I needed for my application. Granted, it took quite a few stages, built in a couple of boxes to avoid any chance of instability due to the high gain.

I did have to pay attention to the total integrated power, to keep the output stage from distorting the noise, but for some sort of Rx bridge, it would have more than enough drive.

This is not something I would recommend. While the theory is that
good RF test equipment should have better spectral purity, and lack of
harmonics, than the radio gear it's testing, my experiences with Wavetek
along these lines have not been good.

> Anyone have a simple wideband circuit that could cover 3.5 to 28 MHz?

My gut reaction is that "Simple" and "Wideband" do not go together
in this context as far as a clean signal is concerned. Suggest examining
the 'Radio Amateur's Handbook' and 'RF Design for the Radio Amateur' (I
think that's the title) for design considerations.

I still think that, if you want to just do a simple QRP CW
transmitter, you'd be better off going with one of the existing designs
in one of those two books (or similar such pubs).

I discovered that you can inject a signal into pin 14 of this chip, removing the necessity for fiddling with the internal oscillator. The internal oscillator is great for LC circuits.....you merely place the tuned circuit between pins 13 and 14, and it flies!
You just have to set the injection level so that the buffered signal at pin 12 is right around 320mV p-p.

Pete

I agree 100% - absolutely one of the very best Amateur Radio CD collections ever put together.

One other that is very good are the CD collections of "Ham Radio" magazine being sold by the ARRL.

I did something similar when I first was licenced in 2001, but I would not recommend it now.

I used my Leader LSG-216 signal generator as a VFO followed by a 1 Watt amplifier that I put together myself. It worked and I had several QSO's with it, but after several RST xx8 reports I found that the signal generator had hum modulation and some jitter. I have later learnt that this is almost inherent in a synthesizer which covers a large frequency range. It has very large VCO gain: MHz/Volts - change in frequency per change in voltage in order to cover the large frequency range. But this also makes it very sensitive to noise in the control voltage.

As a signal generator, i.e. a tool for aligning circuits and so on, this is not a problem.

One must wonder about another "possible" problem as well. If even a fraction of transmitted RF were to get back into the sig gen, it may upset the balance as well causing any sort of problems. Much like when RF gets back into a Power Supply situated close by - creates hum and so on - on the signal. Some Sig Gens may not have enough shielding to protect from this. Their shielding may very well prevent signals from leaking OUT when testing from it's own source, but not designed to fight off Transmitted RF getting back into it. I'm not saying those things WILL happen, but certainly possible. Otherwise, the idea is interesting and I'm sure many others unmentioned have thought of or have actually tried it. I being one.

On another note along these lines, though I didn't see it or hear it, I heard a ham on 2 meters once who claimed to take a Bearcat scanner - a 250 model I believe.. and used it in much the same manner... I'd love to have seen and heard it up close. G.W.

We have been running a community receiver for the
136KHz band for a couple of years in the UK.

A number of amateurs had trouble with noise on the
band (TV, a data ciruit into a hospital and a
mobile phone base-station with faulty SM PSUs just
to name three).

We have a receiver located in a quite part of Crawley
(at our radio club station), and this relays the
whole of the 136Khz band on 2m (135.4KHz = 144.9854MHz)

This is done with an FT-847 running in satellite
mode with the two IFs linked together. We get
quite good coverage over the SE, and good dynamic range.
We are proposing as an experiment to try relaying
a 6KHz segment of the CW segment of 40m band for a
few weeks to get a better feel on the dynamic range
issues.

The system is MB7LF and is licienced as a data
system.

> to be at a loss of components when i start experimenting.

A range of the most common resistor values from 10R to 10M. A total of 500 pcs can already be bought as a "kit" from many shops.

A range of common caps from 10pf to 220uf, but not all that many values. Perhaps a few of each decade (10p, 100p, 1n, 10n, 100n, 1u, 10, 100u) with a few extra in the range of 10p to 100p and 1n to 47n (values used for tuning/filtering).

A slack handfull of general purpose transistors, such as BC547 (NPN) and BC557 (PNP).

Op amps - 741, 324, 358, 386.

A good tip is to visit your local dump. A telly, a VCR and the odd defunct transistor radio can be a goldmine, especially for mains transformers, coils, tuning caps, pots and even hook-up wire.

MOST IMPORTANT - A catalogue from your local radio component supplier. You can't stock everything. The above will alllow you to assemble a few simple circuits, but for anything decent you will still have to buy/beg/borrw or ...

Don't forget to ask them for their PDF library on CD. The catalogues usually give you loads of circuits, pinouts and data. If you are going to spend $15 on a small selection of components, do what you have done here and hint that you are going to buy loads of stuff, build loads of projects, and they usually give you all sorts of freebies.

Hi,
I recently picked up a Henry Radio 2000D Rf Generator, complete
unit, solid stater driver, and 3cx3000 amplifier, High bvoltage power supply.
It was used in sputtering system, at 13.56 mhz.

Im looking to convert it to amateur use. If anybody out there has
already done so, I be interested in hearing from you, Im sure I
can do it, but I wouldn't mind some useful hints, and not recreate the
wheel totally. .

thanks- Chuck (W3FJJ)

I have an unknown crystal I wanted to test for its frequency.

On qsl net I found a test circuit to do just that (I think it is basically a broadband amp).
Initially when I hocked the circuit up on my breadboard the crystal seemed to oscillate at around 27 MHZ.
Then I built the little circuit on a permanent board and now the crystal oscillates at about 9 MHZ and at this point I start to ask myself what am I measuring here. And what assures me that 9 MHZ is the fundamental?

I would appreciate if anybody could shed some light on crystal testing.

Uwe

Your first osc got an overtone and the second the fundamental of 9 MHz and
the the 3rd overtone is 27MHz. It could also be a lower frequency like 3 or
1.5 MHz so listen for these frequencies. The 3rd or other overtones are
slightly higher than an odd multiple of the fundamental!

Message-ID: <f03bf94f.0312041301.463df32a@posting.google.com>
Source record: 30586

Hello there,

For those who have not heard of it yet, I'd like to make you aware of a spiffy new CW Paddle kit being offered by the AZ ScQRPions Radio Club.

This is a little sweetheart made completely of brass and is quite good looking. The price cannot be beat...just $25 shipped in the US.

Pictures can be seen by going to the AMQRP site and clicking on the ScQRPions under "December features."

http://www.amqrp.org

Although I haven't received mine yet, it appears that putting it together should take no more than 2 or 3 hours, and most of the time will probably be spent on polishing the brass.

Happy Holidays to all de WA2AFD

Hi all,

I need to wind 180nH inductor for a parallel tuned circuit I'm
building, since the 180nH factory-made chokes I have don't look up to
the job power-handling wise. This coil needs to handle about 90mA p-p/
500mW maximum dissipation sine current and I've allowed 3 ohms for
series resistance.
Can anyone give me some steer on dimensions, number of turns, core
type and so on? Thanks,

p.

Here are the basic formulas for air core coils. 3 ohms sounds pretty
high for such a small inductance.

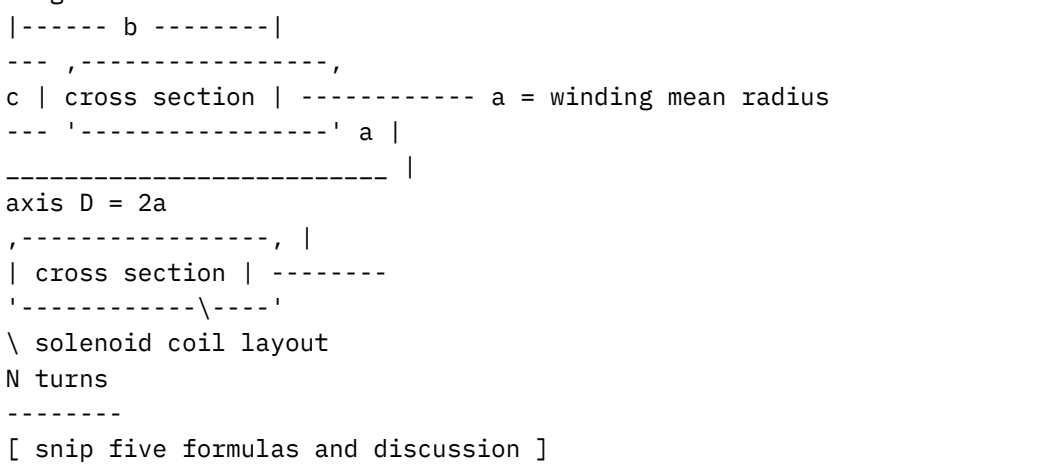
As John has said, that's a very low inductance that should not
present any problems at such a low power level. But perhaps for
a more detailed answer you can tell us the frequencies your coil
will experience. At high frequencies skin and proximity effects
dominate, and these can be evaluated with an Rac/Rdc ratio. If
a ferrite is used its high-frequency core loss can also be modeled
as an inductor resistance.

Do you have any special size constraints? Unless you really need
a miniature size, an air core may be best for 180nH. You can use
the Wheeler equation to experiment with different coil designs.

I'll add some new grist for the mill, with a copy of a portion of
a posting I made 28 Dec 1997, about air-coil inductance equations.

Throughout the discussion we'll use the same dimensional system, based
on the drawing below. Here and in the 14 formulas below, N = turns,
a = mean radius, b = length, and c = winding thickness, and all are
in inches, unless otherwise stated.



[snip five formulas and discussion]

To simplify our lives, Wheeler empirically derived his popular
single-layer solenoid equation, using Nagaoka's equation and
tables. Wheeler's equation is shown below in two different ways.

```
a N^2 a^2 N^2 / 10 b
(6) L = ---------- = -------------- uH / inch
9 + 10 b/a 1 + 0.9 a/b
```

Wheeler says this equation is accurate to about 1% for long coils, or
any coils with (b/a > 0.8). [Confirmed with extensive measurements I
made and posted on s.e.d.] It's easy to solve this equation for N.

A simple re-arrangement adds the concept of winding pitch. This can be
very useful, in part because a low-winding-height multilayer coil can
be treated as a single-layer coil with a higher winding pitch.

```
a^2 p N 1
(7) L = -------- * ---------------- uH / inch
10 1 + 0.9 a p / N
```

Here p is my turn-density pitch parameter, in turns/inch. Incidentally,
this makes clear that for long coils, once you pick a coil-winding pitch,
the inductance scales by N, rather than by N^2. Of course, the length
scales as well. Now solving for N isn't as easy. I get,

```
10 b
(8) N =~ ----- ( 1 + 9 a^3 p^2 / 100 L ) turns
p a^2
```

Alan Fowler pointed out a version of Wheeler's equation, claimed more
accurate, in F. Langford-Smith's "The Radiotron Designer's Handbook,"
1942. In the 3rd edition only, the work of Esnault-Pelterie is detailed,
a Frenchman who followed the "des savants japonais" (i.e. Nagaoaka) for
his derivation of a simple Wheeler-like formula with a claimed accuracy
of 0.1% for values of diameter/length between 0.2 and 1.5. Rearranging,

```
a^2 N^2 / 9.972 b
(9) L = -------------------- uH / inch
0.9949 + 0.9144 (a/b)
```

[snip more formulas and stuff]

OK, there you have a small panaply of equation forms to select from.

(7) is easier to use than it appears at first glance. Let's design
a coil for you. We'll pick wire size #22, which has a diameter of
0.020 inches, prompting us to pick a winding-spacing of 0.04 inches,
or a 25 turns/in pitch. Inspired by a small art brush in my pencil
cup, we'll pick a coil diameter of 0.2", so equation (7) reduces to

```
. 0.01 25 N 1
. L = --------- * ----------------- uH / inch
. 10 1 + 0.9 0.1 25 / N
.
```

```
. 1
. = 0.025" N * ------------ uH / in
. 1 + 2.25/N
```

This formula is more simple than it appears, because the second term approaches unity for coils of more than 10 - 20 turns.

The first term says a 180nH coil requires about 180/25 = 7 turns, so we'll try N = 9, and get L = 225nH * 0.8 = 180nH, right on the money.

That's a 9-turn coil 0.2" in diameter and 0.36" long. It uses less than six inches of wire, has a DC resistance of about 0.008 ohms, and can handle very high DC currents.

Plugging our coil into equation (6) as a test, we have a = 0.1" and b = 0.36" and N = 9, so we get L = 8.1 / (9 + 36) = 0.180 uH, bingo.

Thanks,
- Win

Generally, a crystal is a fundamental frequency below about 15 MHz...

Above that, the quartz crystal starts to be thin enough to make it fragile and prone to being broken. There are ways to make a fundamental up to a hundred MHz or so, but these are usually very expensive crystals and pretty rare.

So, it is most likely that the 27 MHz was the third overtone of the 9 MHz fundamental frequency.

==========

A broadband amplifier type of oscillator may have enough gain, and perhaps a parasitic resonance or so to make it tend to run on an overtone frequency. Generally, build a good circuit on a solid ground and keep the feedback loop set up for low gain on the feedback.

Excessive gain in the system will tend to cause 'strange' results and your experience is not all that surprising.

==========

Given that Citizens band frequency crystals used to be fairly common, I would guess this is what you have.

I highly recommend a J-Pole antenna for FM. I have used them on 2m and 70cm without disappointment. Even with 200mW I can hit repeaters some distance away. They can be scratch made from copper tubing (if you can solder your water pipes you can make this one). I am thinking of one for 6M to run 52.525.

They are 5/8 wave and you get a respectable gain. Just make sure to feed it with RG8 or 9913.

You can compute your requirements and see a model at
http://www.packetradio.com/jpol.htm.
Hope this helps. E-mail me if you have any questions.

I thought the Leader Sig Gens were free running and not very stable. Maybe
it is a new model.
If you simply want a CW TX, why not build the VFO as well?
There are plenty of designs around.
If you do want to use the RF gen , you could always follow it with a low
pass filter.

Thanks, Win! You're a diamond. John's formulae didn't appear on his
post for some reason, but you've given me the info I need to start
winding and be slap in the ball park right away. Great.
BTW, the factory inductors I have already are only about the size of
the newest half-watt resistors, so I was reluctant to chance it. I
know things keep getting smaller and somehow seem to defy the laws of
physics, but just call me old fashioned. :-)
Thanks again.

3983. inductor properties query

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-05 14:57:34 UTC
From: James W <change-to-jw22-at-trlp-dot-com@trlp.com>
Message-ID: <3FD09CDE.1010302@trlp.com>
Source record: 30449

Consider a simple inductive cicuit with a 1v(p-to-p) AC source at 1Hz,and an inductor with Z=1ohm.

The inductors value would be 1ohm=2*pi*1Hz*L, so L= 1/2pi

Looking at the standard Voltage and Current drawings, we see current lagging voltage by 90degrees.

Here's my problem. At 90 degrees, the applied voltage is 1volt. The current is zero. di/dt is 1, and we know that the cemf V=(di/dt)L=1/2p Volts.

So... why if applied V is 1v and cemf is less than 1v do we have a current of zero?

I've got the sneaky feeling that I'm trying to add apples and oranges.

My assumption was that the reason the current lags the voltage is the back emf is being added to (subtracted from) the applied voltage to give us the instantaneous voltage that then drives the instantenous current, but perhaps this whole theory is wrong.

HELP!!

Paul, I really don't think you need to wind your own. For example,
a Coilcraft 1008CS 180nH part is rated at 620mA rms:

http://www.coi1craft.com/1008cs.cfm

The "trick" is that the dissipation is a function of the series
resistance, which is very low (0.77 ohms) as long as the core
doesn't saturate.

If you want to get really silly, their "Spring" inductors are rated
at 3A rms.

Regards
Ian

3987. Kenwood TH-F7E and 9K6 Packet Radio Help please!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-05 16:11:00 UTC
From: tomjay@web.de
Message-ID: <46e6ec0b.0312050811.2ec657@posting.google.com>
Source record: 30453

Hi all,
A friend of mine recently I wanted to start Packet Radio with a
Kenwood TH-F7E and TNC with 9K6.It works fine on receiving but has
trouble with transmitting. It can not get any connect although PTT
works fine and the TNC also works with another radio.
It seems there is something wrong with the outgoing signal of the
TH-F7E.Maybe the gain is too low?
Anybody experienced the same problem with that handheld from Kenwood?
Any help would be greatly appreciated!
Thanks and 73 from Tom, DL2HRF

at the 90deg point, the I curve is crossing the zero point. It's a sine wave. Sine waves of amplitude 1 have a slope of 1 at the zero crossing, no?

No. If the period is 1 and the peak to peak amplitude is 1, the only
way the slope could be 1 would be if it were a saw tooth wave.

John,

It's been a while (20 years) since I took calculus, but I'm pretty sure
the slope of a sine wave at the zero crossing is +-1.

What value do you believe the slope to be?

3994. Large roller inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-05 18:52:07 UTC
From: rob34 <rob34@infinet.com>
Message-ID: <vt1kuss9smdc92@corp.supernews.com>
Source record: 30460

I have a big roller inductor made by E.F.Johnson model 226-5. It would make a great coil for the homebrew linear as it could easily take 5kw and has enough inductance for 10 through 80 meters. It is a beautiful silver plated coil in excellant shape that measures 13.5 inches from one end of the shaft to the other and the coil is 3.5 inches in diameter. It measures 8.5 inches from end to end of the insulated plates which holds the coil itself. Very heavy duty construction, just a little too big for my needs. You can go to this website to see pictures on it: http://photos.yahoo.com/rob34115 and look at Rob`s photos. There are three pictures of it and some electrolytic caps and parts for a HV power supply I am selling. Please make me a reasonable offer on these items!

You forgot to specify by far the most important characteristic - the inductance.

At least you could give the number of turns. Otherwise it's a pig in a poke.

Please allow a prospective customer to decide what bands can be tuned.

>
> Is it as simple as this or am I missing something blindingly
> obvious ?? Is 1-2" a suitable spacing between the tubes & glass plate &
> will normal, thin, glass sheet be suitable ??

I use regular 2-3 mm window glass, I place the pcb board with the artwork on
my washing machine (nice flat white surface, good in low light), cover it
with the glass and place the light, a 12 cm long unit, on two wooden blocks
about 6 cm above the PCB board.
Hit the switch, leave the room and come back when the time is up.
For large boards I have to shift the lamp every few minutes for an even
exposure.

I have done quite a few exposures this way and would recommend this
primitive appraoch before I set out to build anything. Experience will then
guide you how to do your "final" exposure box.
Besides, my approach is dirt cheap and dissappears completely when I am
done, nothing much to store.

regards Uwe

As can be seen from the pictures there is 14 turns at 3.5 inches in diameter which is more than enough inductance for 10-80 meters. I am not sure what the actual inductance is, you might be able to go to a website with the model number and get the exact specs. WB8VWI Rob

3998. Help an old Ten-Tec tranceiver argonaut II in a homebrew transverter project

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-05 20:29:51 UTC
From: Peter PE1CUO <dedigitalestedenservice@xs4all.nl>
Message-ID: <3fd0eb64$0$207$e4fe514c@news.xs4all.nl>
Source record: 30464

Having made a new transverters for 2, 70 and 23. and planning to use it with a older sw-tranceiver using for MF covering 20-30 Mhz.
So that I have on 70 and 23 a coverage of 10 MHz and the advantage of the MHz digit to be corresponding with the actual freq in use en having the front end tuneble.
So tuned to 20.000 MHz i430.000 and 21 Mhz= 431.000 etc.

Now a days you find, I thought, on the web for every tranceiver a Mod to release the TX out of the ham band
I had in my mind to make the switching following the idea when the transverters are engaged, tx out of ham band is released and when tranverters are switched off or not connected the out of band TX-band tx is blocked to prevent transmitting out of the band, to prevent me of doing something wrong.
Having still left a not big digital Ten-Tec tranceiver, an Argonaut II (535) seems be a little sister of an Delta II (536). which nice having adjustable bandpass and bandwith.
Before the operation of starting to buils the transverters I already had a look in the manul and there they say it is an easy job expanding it for full coverage TX.
It's a very nice rig on hf and would provide me with a very MF for my trnsverters
Made everything ready for the receiving side, it really works very nice.
Coming to transmit part I provided a low level 10 mW drive output to my transverters.
So now I started looking on the web for mods, for the tx frq expansion, I could find mods for nearly every trade mark you can think of, but not for the Ten-Tec and certainly not for Argonaut/Delta II.

Tried to get it from Ten-Tec, but no luck so far..

Beside this, I am looking for information about the commandset and the communication protocall to make a little program to control it from a homebrew webserver stamp processor.
They were selling an interface 305 to connect a computer and the information was only packed to the interface 305 they were selling in the past, as this item also being discontinued, I also have trouble finding this info.
The hardware interface is according to info on the web Icom compatible, making an inferface should be a problem, but on the software side I could find any real info for things like a command set etc.
Now can only use it to transmit from 438 to 440 and simular on 23 cm and on 2 m I can use it at all.
So I am about to break up the rig and build my own logic for thing, not being able to find this info, (I tried finding out looking at the printbord and the schematic but even these differ and could find the right solution)

So who can help me with this modification and info on the software side?

Peter, pe1cuo

Well, I wish I could do a good drawing here... but
If we assume that at 0deg, voltage is zero, then, at 90 degrees, voltage
is max. With a perfect inductor, current lags voltage by 90 degrees, so
current is 0. Current is a sine wave. So.. why isn't di/dt==1 at this point?

Hi,

You have declared a frequency of 1Hz (i.e. one cycle per
second) for your source.

OK, now draw a sine wave with a triangular wave of the same
peak amplitude inside it. You should be able to see that the
initial slope (di/dt) of the triangle is much greater than one
amp per second, in fact it is four times that since it reaches
its peak in a quarter of a second. Now look at the sine wave - at
the crossing it is steeper than the triangle.

Cheers - Joe

The sine wave voltage was specified as 1 volt peak to peak (+- .5
volt) The impedance of the inductor was specified as 1 ohm. So
current peaks at +- .5 amp. A sine wave that has a peak value of +-
.5 and a period of 1 unit of time has a peak slope of pi/sec or
2*pi*(peak amplitude)/period.

<< Initially when I hocked the circuit up on my breadboard the crystal seemed to oscillate at around 27 MHZ.
Then I built the little circuit on a permanent board and now the crystal oscillates at about 9 MHZ and at this point I start to ask myself what am I measuring here. And what assures me that 9 MHZ is the fundamental? >>

Uwe-

As has been pointed out, you probably have a crystal from an old CB set, designed to operate on its third overtone. At one time CB sets were sold with only a few channels. You purchased transmit and receive crystals for the channels of your choice, to supplement the one that was supplied with the radio.

How do you know the 9 MHz is NOT an overtone? The observation that crystals usually only operate at an odd overtone, might lead you to believe this. For a 9 MHz overtone, the fundamental would likely be at 9/3, 9/5 or 9/7. There may be odd multiples of these frequencies that fall near the observed 27 MHz frequency, but they would be relatively high multiples.

One way to tell would be to incorporate tuning components to select a desired frequency. If the crystal will oscillate with tuning set to 9, 27 and 45 MHz but not at 3, 1.8 or 1.286 MHz, then it is reasonable to assume 9 is the fundamental.

<< I need to wind 180nH inductor for a parallel tuned circuit I'm building, >>

Paul-

I suggest you find some stiff wire, wind about five turns using a pencil as a form, and stretch or compress it to tune the circuit.

If you want a more stable inductor, then wind it on a high value, one or two watt resistor. Once the desired inductance is set, put some kind of varnish (coil dope) on it to hold the winding in place.

Thanks, Ian, but it only took about 15 seconds to wind the coil
according to Win's spec and more importantly, winding my own enables
me to take a tap off it, which I believe may be necessary in this app.

OK
What if a hypothetical homebrewer needed to create a slugged coil inductor for his homebrew receiver, and he wondered how many turns he would need to create a nominal inductance of 4.5uH?
Suppose he found a ceramic form at Antique Electrical , a 1 5/8" size that was just perfect? (copy this in your browser)
http://www.tubesandmore.com/images/inv/P-C210.GIF
Where would that hypothetical homebrewer find how many windings he'd need?
Most of the formulae he (that hypothetical homebrewer) found was directed it appeared to larger coils, like for crystal radio main coils.
Can anyone point that hypothetical homebrewer to the right formulae?
Thanks (on behalf of the hypothetical homebrewer)
Tom

X sub L is inductive reactance, yes that varies with freq.
L is the fixed value inductance.

though there is some parasitic capacitance between windings that does effect the
resonant freq. a bit. www.coilcraft.com gives guidelines to this.

We're talking a small air-coil here. As SRF is approached the
reactance does depart from the expected linear plot, but that's
because one should have considered X_C as well. Say, you're not
talking about an exotic high-frequency region where the physical
diameter of a coil may drop slightly due to proximity effect?
Sheesh!

Source record: 30481

I've got an HP 8640B Opt 2, and am quite satisfied with it's performance but
this one doesn't go below 500KHz since it doesn't have Opt 1. I have
several choices and would like some user opinions if anyone has a
comparison. I can buy an HP 11710B down converter which will divide the 50
to 61 MHz band down to 10 KHz thru 11 MHz or an HP 11710A that divides 5 to
5.5 MHz to 5 KHz thru 500 KHz. The HP 11710 A&B are quite differnt in size,
appearnce and I wonder if the B is that much that I should only consider it?
In addition, I could try to find an HP 8640B with Opt 1 that includes an
internal audio oscillator that covers 20 Hz to 600 KHz, and sell my unit.
But I don't think I'd have phase lock available which is nice but probably
not mandatory. I'm not sure how the Opt 1 works with the attenuator.
At the present time I'm using a HP 606A a sizeable beast
that goes down to 50 Kc. I also have an HP 3586C which is quite good
as a Sig Gen, I got it becasue I wanted to listen to LF! So I is it an
11710,
an Opt 1 trade or something else, I wouldn't mind recovering some space!
Any user experience with these units appreciated.
thanks

Source record: 30483

Hi gang,

I've just developed a three stage RF amplifier for 40Mhz and the final PA stage is shown below. The maximum power transfer occurs when the load resistor has a value of 140 ohms whereupon it dissipates a thumping 475mW of RF power! All well and good, but I need to radiate as much of that power as I can - with only a telescopic whip antenna. So I snip the load resistor out of circuit and the following questions arise:

Where do I take the feed point to the antenna from? I realise I don't have a hope in hell of matching 140 ohms without an "L network" or whatever, but is that really necessary? Could I get away with taking the antenna feed direct from a tap off the tank coil?

I only *need* 50mW ERP so am not *too* bothered about losing most of the useful power.

I'm not familiar with this particular model, but my own experiences
with other signal generators lead me to believe that they are very
poor singal sources for this type of application. The main problem
AISI is freqency drift. You may get some reasonable stability after an
hour-or-so's settling down, but many people with whom you wish to
communicate via CW will be using *very* narrow filtering and will
constantly lose your signal if they don't repeatedly re-tune.

I'm still none the wiser. Unless you're taking into account stray
inductance from the leads, of course. But the *body* of the inductor
by itself must surely be of a fixed inductance. One does not come
across coils rated at "3uH @ 150Mhz.", for example!
Are you talking about the impact of stray L from the lead-lengths?

Hank-

I'm not that familiar with the specs, but it looks like the lowest band on the 8640B is 250 to 500 KHz, regardless of option.

The variable audio oscillator option has its own output level adjustment, but I don't think it is calibrated like the main RF output. It certainly doesn't go through the main attenuator except as modulation on the RF! I'm not sure, but the variable audio oscillator's output may be 600 Ohms rather than 50.

When I've tried adjusting the frequency on the variable audio oscillator, I've found it touchy. You definitely do NOT have phase lock on that oscillator. It would be fine for use with AM and FM modulation, but not the greatest as an LF RF signal where accuracy is a bit more important.

I can see using it with sufficient output to drive the counter's external input, but with an external attenuator to set the impedance and level for your application. It might work, but I wouldn't be happy with such an arrangement!

The low end on mine, with options 1, 2, and 3, is just above 447 kHz.
That appears to be the designed low end, so that the 8640B could be
used for IF alignment.

There's an option that controls whether the _high_ end is 512 MHz or
1024 MHz, but that's different.

Can you use a function generator, or a test oscillator like the H-P
651 for frequencies below the lower limit on the H-P 8640? it is
something that comes in handy for other things anyway. The test
oscillator would stack on the 8640, its in the same style H-P cabinet.

5 each 7.5 volt 10 watt zeners in series might work. Or you might
build a power transistor circuit that current amplifies a small 35
volt zener. It all depends on the details of the circuit. That is
one hell of a bias zener.

A simple shunt regulator using a TL431 and a pass transistor will give adjustable voltage and better regulation than a large zener diode, and is actually cheaper.

There's a lot of information on my website, at:
http://www.ifwtech.co.uk/g3sek/boards [some commercial content]

Well, just about anything is "non-linear" if you measure it accurately
enough! But is it really true that the *inductance* of a "small air
coil" is "dramatically" non-linear with frequency as you stated?

Intuitively I'd have thought the answer was plainly No, but I'm certainly not technically savvy enough to be confident about that. But I strongly suspect that the thread is already ovedue an unambiguous definition of 'inductance'. Where's John Woodgate when you really need him...<g>.

>actually act like a capacitor, believe it or not.

This is only an artefact if you try to determine the inductance of an inductor by measuring the reactance of that component at some specified frequency. The inductive reactance (Xl=2*pi*f*L) will grow in a linear way towards a positive value depending of the frequency.

Since the parasitic capacitances are present, the negative capacitive reactance (Xc=-1/(2*pi*f*C) will complicate the situation. When approaching resonance in a parallel resonant circuit, the reactance goes to +infinity, switching rapidly to -infinity as the resonance frequency has been passed and slowly approach the linear drop of the negative capacitance at frequencies far above resonance.

One can still argue that the inductance and inductive reactance are as well as the capacitance and the capacitive reactance are still there as separate entities, but we can not measure them separately from terminals of the coil. Thus, this is an artefact of the measurement method.

Thus, the inductance should be measured at a low frequency to avoid the capacitive reactance. On the other hand the capacitance should be measured at a high frequency well above resonance to avoid the effects of the inductance. Or just measure the inductance at a low frequency and determine the capacitance from the resonance frequency and inductance.

While inductance and capacitance are frequency independent, the resistance of a coil will vary with frequency due to the skin effect, since at higher frequencies, the conductivity of the inner part of the conductor is not used.

Bill, it's one thing to say a coil's reactance is non-linear, but it's another to assert its inductance varies with frequency. As I responded before, the inductance of air coils varies very little with frequency. I know this having made many types of air coils to verify the standard inductance formulas, and precisely measured them over a 60Hz to 50MHz range. Earlier in the thread I pointed out the effects of SRF (self-resonant frequency), due to the coil's parallel capacitance. It's not useful to my thinking to characterize those two components as one part, and it's little surprise one gets into trouble when attempting to do so. A similar statement can be made at very low frequencies where the dc resistance exceeds the reactance, and the coil is best considered as two separate parts in series.

The capacitance and dc resistance are both simple and rather obvious considerations, with straightforward solutions. In contrast, a subtle and difficult issue in air coils is modeling Q or loss vs frequency.

The concept of ac resistance is often used for loss, and is expressed as a ratio to the dc resistance, Rac/Rdc. Predicting that ratio is the tough part, including not only the well-understood skin effect, but also the relatively obscure and often larger proximity effect. Further complications enter if one uses multiple wires, and how they are wound, or if one uses any of the many types of litz wire.

Thanks,
- Win

Skin effect applies equally around the periphery of each wire,
what you've described above is the more serious proximity effect.

The original question was about a zener diode, ie a shunt regulator. I wasn't aware that a 317 plus a transistor could be configured to emulate a zener... can it?

The TL431 certainly can.

>_____
>
>If you're going to use such things, you must protect them against
>inadvertent arcs. One good arc and they will be history.

Normally an arc from the B+ supply of a grounded-grid triode is no threat to the cathode bias device. Arcs inside the tube will ground out to the grid, and external arcs to the chassis; and then the current flows back to B-minus. The cathode and the bias device are not part of that current path, so the bias device is not at risk.

The exception is if an internal arc is severe enough to burn right though the grid (I've seen that in a mesh-grid tube) or if the current is high enough to drive the local grid potential positive. Then some of the arc current - perhaps tens of amps, peak - will flow down through the cathode. In such extreme cases, no bias device is likely to survive... at least, not without some additional protection.

That's why, whatever bias device you use, an 80-cent varistor connected from cathode to chassis is a very good investment.

> A big, fat
>zener on the other hand, is relatively immune to such abuse.

"Relatively" in this context is hard to judge. In most cases, the bias device survives because it wasn't actually under threat - see above. If a device does fail, it's only guesswork to say how a different bias device would have fared in the same amplifier.

A more reliable picture emerges from a larger number of amplifiers. There are more than 350 Triode Boards out in the field, with tubes ranging from the 2C39 to the 3CXP5000, and they all use basically the same TL431/TIP147 circuit protected by a varistor. Between them, these boards have seen a lot of arcs, and there's no indication that the bias circuit is notably fragile. Certainly there are occasional failures -

but in those cases it seems likely that a big, fat zener wouldn't have
survived either.

Yes, I'm sure no one here disputes that coils behave like capacitors
above their SRF and capacitors behave like coils above the SRF. That's
not news. And it's to do with the *reactance* of the part, not its
inductance. AIUI, inductance is pretty much stable over the frequency
spectrum. You appear to be the only person here who claims otherwise.

That's *reactance* giving rise to that effect, not inductance!

Youall seem to be hitting all around the 'problem'. A coil has 3 components, the resistance of the wire, the inductance, and the stray capacitance. As the frequency is changed from DC to low AC to RF each component has more or a less effect on how it acts in a circuit. The actual value of each does not change, just the effect on an external circuit.

For small coils at DC the reisitance is the major item that will be seen by an external circuit. At low to medium frequencies the inductance will be the major factor. At very high frequencies the capacitance may be the major factor. At self resonant frequencies , the tuned circuit effect takes over.

No, you are talking about the *reactance* ("reactive impedance"). We
have been talking about the *inductance* ! They are not the same
thing.

If you model a real-world "coil" as a perfect capacitor in parallel
with a perfect, *fixed*, inductor, it will behave as you
describe. (Well you need a resistor too if you don't want infinite
"Q"!)

Real "Inductors" do indeed have a self-capacitance too, which will
make the component deviate from that of an ideal inductor in the way
that you describe. But this in itself does not make the inductance
(i.e. the inductive part of the reactance), vary.

No, it does not. I'm afraid you are using the word "inductance" in a
different way from everyone else :)

> It's a simple law of physics; there is no way around it.
> And *above* the self-resonant frequency, the choke actually behaves like

Yes, because at high frequencies the current goes through the
capacitance of the coil rather than the *fixed* inductance.

(Uh, by the way, you do know who you are arguing with, right?)...

Now you have gone and said something that is simply not true. The
small inductor has a nearly fixed inductance with a parallel with a
nearly fixed capacitance. The combined impedance of these two fixed
reactances produces a nonlinear impedance, but there is nothing about
that impedance that implies a large change in either the inductance or
capacitance of the combination, at least not until you get to so high
a frequency that the winding is a significant fraction of a cycle
long. The rise in impedance near resonance does not exhibit the same
phase shift that between voltage and current that a large inductance
would have.

Agreed. One usually specifies an inductor that is measured at a
higher frequency than the one being used.

<< Where do I take the feed point to the antenna from? I realise I don't have a hope in hell of matching 140 ohms without an "L network" or whatever, but is that really necessary? Could I get away with taking the antenna feed direct from a tap off the tank coil? >>

Paul-

You could use a tap, or add a winding to the coil. If it could be assumed that the antenna was 50 Ohms, the impedance ratio needed would appear to be 140/50, or 2.8. Therefore turns ratio would be 2.8 * 2.8, or almost 8:1. In other words, if the coil had 8 turns, the 50 Ohm tap would be at one turn.

With a second winding, the capacitor would not be needed to block DC. However, it would be a good idea to include a variable capacitor as Clive suggested, to tune out any series reactance.

Remember that the telescopic whip is only one half of the antenna system. You need some kind of counterpoise (ground) to balance it.

Hello,

does anyone have some information about a general radio GR-1452 programmable attenuator with max 79 dB of attenuation?
What is the frequency range an what is the maximum input level.
I can get my hand on one of those,but i want to know if it suits my needs.

I want to use is with 27 dBm input level and want to use is for 70 cm and 23 cm.
Every information is welcome.The internet gave no real results (exept where to buy it).

Please reply in this group because the e-mail adress is not valid anymore (Spam)

<< Does anybody have, or know where I can get, the
spec.'s and pin-out for an old Ovenaire model
OSC-85-11 10MHz oven controlled oscillator module?
It came out of an old junk Fluke model 7261A
frequency counter, >>

Leland-

I have the Fluke 7220A counter that uses the same oven timebase options as the 7261. According to the 7220 manual, options 131 and 132 ovens are both used on the 7261. I have the Ovenaire OSC 85-22, Fluke option 132. Take a look at a chart on the bottom of the 7261, to see which option is checked.

If the OSC-85-11 is from Option 131, it is the "Low Power Oven Time Base". The oscillator is Fluke part number 516116.

Counter Specifications with this option:
Nominal Frequency 10 MHz
Aging Rate +/- 1X10e-7/month*
Accuracy with Temperature +/- 1X10e-7, zero to 40 degrees C
Line Voltage +/- 2X10e-8 for 10% line variation
Warmup 10 minutes +/- 5X10e-7, 20 minutes +/- 3X10e-8
Battery Operation +/- 5X10e-8.
* after five days continuous operation

There are five leads, three near the center and two near the end of the OSC 85-22. In the 7220 diagram, pins 1 and 13 are connected to ground, pins 6 and 8 to +5 Volts and pin 7 is output. From this, I would guess that the center pin of the three together, was the output. The manual doesn't have PCB layouts in sufficient detail to see which pins go where, so I would have to disassemble the counter to find out for sure. Perhaps an Ohmmeter check of the three pins with respect to ground, would ease your mind.

Nonsense. General Radio had a nice little formula way back
before 1956 for finding the distributed capacity of an inductor.
It was published in the Green Bible (ITT Reference Data for
Radio Engineers, small format, dark green hard cover). I used it
years ago and earlier this year and many times between.

Write on the whiteboard 100 times: Inductance does not change
with frequency...reactance changes with frequency.

Now if someone actually wants to WIND COILS, I have a little aid
for tiny ones wound on common screw thread forms that was
published in Ham Radio magazine. Has measured Qs over
frequency as well as basic inductance. I'll attach it to private e-mail
(PDF) to anyone that requests it.

Using common screw thread formers and solid wire allows a good
repeatability between bench and application. Forms can be anything
from a 4-40 bolt to a common screw-thread lamp base.

Folks in here are getting too wound up...and coiling to strike. :-)

4048. Re: Max nr of poles in CW-filter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-07 19:08:32 UTC
From: Ken Linney <Ken.Linney@btinternet.com>
Message-ID: <bqvtrfcgi1@sparta.btinternet.com>
Source record: 30515

Hi Heikki et al

I have some info from Bill Carver, W7AAZ's article "Why Crystal Filters" and he describes a 16 pole SSB filter and using a "meshing" technique and ended up with an xtal filter with the following spec: Thats impressive!

BW : -3dB @ 2.23 KHz
BW: -6dB @ 2.42 KHz
BW: -60dB @ 2.89 KHz
BW: -80dB @ 3.24 KHz

A Shape factor 1.19 (6:60dB)

And of main interest : 1.8dB insertion loss (50 Ohm)

Now obviously the main criteria are the initial "Q" of the crystals chosen. Bill used DigiKey 4.433Mhz types and bought 100, HC-49 that had an average "Q" of 112,000.

To determine the minimum Q xtal for the application required then refer to the following:

Qmin = Fo / BW

where Qmin in the minimum xtal requirement - but that gives infinite loss definitions!

What Bill has measured for example is that using the above for 2.1 KHz filter centered on 8Mhz then the minimum Q xtals from any batch you have must be at least :

8,000,000 / 2100 = 3,810 and for the 14 pole version that relates to about a 3dB insertion loss. Now for the CW filter! consider 500 Hz at 8Mhz then Qmin would be 16,000 and even a 6-pole Chebychev with Q's of 150,000 would give rise to the overall filter loss of over 12dB's. Depending upon what ripple values you choose then if and a big if these days!! (as cheap xtals are getting worse Q's! whenever I test them!!) back to the story!: If same filter at 500 Hz BW had xtals having Q = 320,000 (you need luck!!) then expect overall filter loss to be 4 - 5 dB.

I had been experimenting (not recently) with xtals on 6.144 Mhz with unloaded Q's of around 100K - must get back to that project as I spent hours checking batches of those two legged critters!!

..... Best wishes

Ken, G3UDA

I'm here today, but I was away all last week. I don't think I can add
much; small air-cored coils have inductance independent of frequency up
to about half the self-resonant frequency, when deviation begins to be
noticeable. Low-frequency iron-cored coils are quite another matter; the
inductance varies with frequency, voltage, temperature, previous history
and the state of the tide on Europa. Also, it comes in two varieties,
series equivalent and shunt equivalent, and you'd better get the right
one for your problem. As the inductor gets 'worse', at lower
frequencies, the shunt equivalent tends to infinity, which puzzles
students no end.

This is a 1920s problem. Just as you parallel capacitors of different
type, electrolytic, metallized foil and ceramic, to get a wideband
component, so you put inductors of different construction in series to
get a wide band component. You can wind them all on a bit of wax-
impregnated dowel if you like. (;-)

It would be better to say 'equivalent inductance', being the value L -
1/(w^2C). L = true (series equivalent) inductance, C = self-capacitance
(treated as lumped in parallel with L) and w = 2[pi]f = angular
frequency.

Resistance ignored, as irrelevant at this level.

This is what happens to the *parallel equivalent* inductance. The series
equivalent goes down as the frequency increases, and goes to zero at
resonance.

I was very interested in all that talk about how much Tektronics sucks although after reading most of it I don't think it reflects my concerns.

I just recently bought an old 465 and am learning to use it and I was wondering if with so many knowledgable folks somebody could recommend a good book which would teach the intricacies of using this level of equipment. Hopefully with good hands on examples and not on a trivial level which tells me to wear eye protection when using any Tektronics product.

Regards from snowy Maine

Here are three books that are pretty good:

Hands-On guide to Oscilloscopes by Barry Ross
McGraw-Hill
ISBN 0-07-707818-7

The Complete Book of Oscilloscopes 2nd Edition by Stan Prentiss
Tab Books
ISBN 0-8306-3908-X

and

Troubleshooting with your Triggered-Sweep Oscilloscope by Robert Goodman
Tab Books
ISBN 0-8306-3891-1

I like Ross' the most for basic explanations.

I disagree. The inductive component of the impedance remains
essentially constant through resonance. What is non ideal about the
inductor is that it does not exhibit just inductance, but a parallel
combination if inductance and capacitance. Ignoring the capacitance
and calling the effect variable inductance is just not as accurate a
way to describe what is going on.

But the impedance of a coil near resonance is not well described as an XsubL. It is a combination of XsubL and XsubC, including their different phase shifts.

You cannot just measure the magnitude of impedance of a coil and assume that you are measuring pure XsubL. You have to prove that this is the case by some other measurement, like the phase relationship between voltage and current.

The important thing here is the "subL". It applies only to the
inductive part of the overall reactance.

> Are you saying that formula is correct as some (low) frequency but
> incorrect at another (high) frequency?

No, it is always correct. It is practically the *definition* of
inductance so it had better be!

> I'll say it another way: Inductance and reactance are directly related
> to each other by the (2 pi F) factor. Given one (inductance or
> reactance) you can calculate the other. There is no other way.

No. Because the "reactance" (without the sub-L) now has both inductive
and capacitive terms. When you measure the *overall* reactance of a
real life coil you are measuring the effect of *both* terms. You
cannot measure this combined reactance and then just plug the number
into a formula which ignores the capacitive part. You have to use the
general formula which include the self capacitance.

Ignoring the coil resistance (i.e. we have infinite Q) the correct
formula is something like:

```
Xtotal = 1
--------------
|1/Xc| - |1/Xl|
```

Where Xc = 1/(2 pi F C) and Xl = 2 pi F L.

Hopefully you can see how Xtotal behaves as you describe, even with
constant L.

>physically separated either, since the parasitic capacitance is always
>present between adjacent windings. I would not call it an artifact of
>the measurement method, but rather an artifact of the coil itself.

The problem with circuits containing both inductances and capacitances
is that in one kind of reactance, there is a +90 degree phase shift
and the other with -90 degree phase shift. Thus, when these are
combined, they partially cancel each other, producing different
magnitudes and some phase shift between -90 and +90 degrees. If only
the resultant magnitude is used (and the resultant phase is ignored),
this would give the false impression that the inductance changes with
frequency.

Instead of using the resultant reactance on some specific frequency,
the inductance could be measured in a different way.

When a DC current I is flowing through and inductance L, the energy
stored in the inductance is W = I*I*L/2. This could be used to
determine the inductance L.

One way to measure the energy W would be to cut the DC current through
L and after disconnecting I, dissipate the energy in some kind of
integrating load across L. Even if there is a significant capacitance
across L, no energy is initially stored in C, since during the steady
state condition, the current I would be flowing through L, but there
would be no voltage difference between the ends of L (assuming R=0),
thus all energy in this parallel resonance circuit is stored in L.

After disconnecting the DC current I, the energy would bounce back
between L and C, but finally it would be dissipated by the external
load. The same energy would be dissipated in the external load even if
C did not exist (assuming zero losses).

Thus using this measurement method, the value of L would be the same regardless if C is present or not.

Thus, getting a frequency dependent L, is a measurement artifact in the method that you are using.

I assume that you are referring to DC biased iron cores (without an
air gap) or some high permeability ferrites with a strong DC bias
current. These do indeed show a variation of inductance depending on
the DC bias current.

No, you are neglecting the phase. The two cases would have very
different phase shifts (the current would be out of phase with the
applied voltage, by different amounts), depending on whether you were
below, at, or above resonance.

Yes it can. This is what a network analyser or impedance bridge does,
(as I understand it, I've never actually had to use either!).

At low frequencies the black box would be inductive. The current would
lag the voltage. At resonance the voltage would be in phase with the
current (the black box would appear resistive). At high frequencies
the current would lead the voltage. It would appear capacitive.

Not if I can measure both the magnitude and phase relationship of the
device.

If I can only measure the magnitude of impedance at one frequency, I
can't even tell if the device is predominately inductive, capacitive
or resistive. So it would be a bit silly to call that magnitude an
inductive impedance.

> And yet, at some other (lower) frequency, they will measure quite
> differently. This is the basis for my observation that inductance does

Only because you are willing to confuse complex impedance with
inductive reactance.

4065. Circuit Board Specialists Kit

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-07 21:38:43 UTC
From: "Clair J. Robinson" <cjr.nocrap@visi.com>
Message-ID: <3FD39DE3.3DE6871A@visi.com>
Source record: 30532

I recently came across an unbuilt kit from the subject company. It is for a "Universal QRP Transmatch". The front panel measures 2 3/4 by 5 and is etched from circuit board material and has the ARRL logo either side of the controls. Unfortunately, I have no assembly instructions but I do have the invoice and know that it was shipped on 3/12/82. I search of ARRL publications for the previous 10 years produced no match but the QRP transmatch article in QST for October 1973 may have been the inspiration.

The QST design used 3 toroidal tapped inductors but there is just one core in the kit. Both designs used a 12 position switch to select the inductance. As I seem to be missing any knobs that would fit the miniature variable capacitors, I may also be missing the other cores but I don't think think so. I am at a bit of a loss with regard to the inductance winding specs though I guess I could eventually find something that works by trial and error.

Does anyone have any info on this kit? Or on Circuit Board Specialists? They don't seem to be in business anymore from what I can tell.

Thanks in advance. If you wish to reply direct, remove the obvious extra element from my email address.

Thanks soo much, but it may have to be a used book from a hamfest or such,
as another poster here suggested, the first book on the list goes for $120!

Older books are also more likely not to talk much about the new fancy
possibilities a 465 doesn't have anyways.

Wow! I picked that book up at a hamfest brand new a few years back for $21.95, the list price.....I don't know what is so magical about this book that copies are selling above $100 (in some cases way above...). It's a great reference but I wouldn't pay more than cover price for it.

Sorry 'bout that, I had no idea.....just looked at the cover price when I was listing recommendations.

Picked up a used IC-251A 2M all mode rig a few weeks ago. I left the radio on today and when I went back to it the evening, the display was blank and by listening, it appeared that it could not be tuned. Turned rig off and back on. No joy. Unplugged from wall outlet. Full joy! obviously the rig is partially powered up as long as it's plugged into the wall. Anybody see this problem before? If so, what was your fix. Don't really feel like tearing into full blown troubleshooting. Guess I would start at the power supply, but most likely trouble is in digital logic area somewhere, or around CPU. Bummer. Hate when that happens...

Hi guys,

How does one go about measuring (with a reasonable degree of
accuracy) the radiation resistance of antennas? And when I say
"antennas" I mean any radiator from a balanced dipole through to a
random length of wet string with a damp matchbox for a ground plane.
Must it be done with a noise bridge or is there another way that
requires no special test equipment (aside from a scope/sig.gen etc.).
I'm primarily interested in checking out highly *non*-ideal antennas
for use in non-ideal situations/locations.

Say what???? You have two variables that satisfy the equation:
XsubL and F
The equation does not mean that L varies!!!!!!!!!!

Yes, "got it." Unfortunately it doesn't explain your hair-brained
theory of variable inductance within a fixed inductor.
In fact the effect you've been trying to decribe appears to be no more
than an esoteric and practically-insignificant technicality - *if*
indeed it exists at all.

The question wasn't so much ZENER so much as it was BIAS -- the LM317HV or TL783 will go much higher than an LM317.

this level of equipment.

Here's a thought for you. If you don't get QST
then you should sign up and get it. Every month
they have a tutorial on basic electronics using
your basic meter, function generator, scope etc to
make measurements. I would assume from your
comments that you don't have much experience using
test equipment so these tutorials are a good way
for you to learn and have some fun doing it too.

A second idea would be to check out your local
technical college or university library. They just
may have books that cover the use of a scope for
general trouble shooting of stereos, TV's etc.
That would be a good way to learn the many ways a
scope can be used and it may not cost you a penny
to check-out the books for home study.

Good luck;

This was best posted to rec.radio.amateur.antennas but...

For ordinary wire antennas operated independent of ground and without loading coils, the radiation resistance is very close to the resistive part of the feedpoint impedance. Any number of instruments can measure this with reasonable accuracy. A noise bridge or some of the popular impedance bridges (AEA CIA, MFJ, etc) can do it.

If the antenna has loading coils, or is operated against ground, then the losses in those (sometimes greatly) affect the measurement.

In either case, "special" equipment in the sense that it's more than a scope and signal generator *is* required. Very often transmission lines are a part of the equation and their effects need to be accounted for as well.

I suspect that the more non-ideal the antenna, the more difficult the measurement.

While this probably does not have anything to do with your problem. The
Icom rigs of that series have a logic circuit that is running on a battery .
If the battery goes dead the rig will quit and you have to send it back to
Icom for a new battery and new programming. There is (was ?) someone that
makes a memory circuit that does not depend on the battery.

Bill, I sincerely apologize for hurting your feelings unintentionally
with my clumsy comment. I should have kept strictly to inductors and
away from anything that could have been interpreted as a personal
attack.

You may not have an impedance bridge (a limitation) but I and others
do have one and they separate the components of an impedance,
especially if you take two or more readings at different frequencies
and solve a bit of math.

Not only that, the inductance can vary with the AC voltage applied, most
notably when saturation is approached, but it can also happen with
silicon iron at very low inductions. Nickel-iron alloys don't normally
show this 'bottom bend' effect.

The original question was specifically about cathode bias for a grounded-grid power amplifier. That application requires a two-terminal shunt regulator like a zener diode.

If there is a way of configuring a 317-family series regulator and a power transistor as an adjustable two-terminal shunt regulator, I'd be genuinely very interested to learn about it.

Are you really interested in the radiation resistance or are you
actually trying to figure out the efficiency or total radiated power
of the antenna ?

One way would be to first measure the total radiated power. To do
this, you would have to measure the EiRP to all directions and
integrate it. If the measurement is done in the far field, a
calibrated magnetic probe would be enough, but at closer distances,
additionally the electric field would have to be measured with a
reference dipole.

At short wavelengths the antenna can be put on a rotating table but
for instance to measure the radiated power for an LF system, you would
have to fly around in a plane with DGPS navigation and make the
measurements from all directions.

If the antenna has a symmetrical or otherwise well known radiation
pattern, the number of measurements could be greatly reduced.

When you have the total radiated power and then measure the input
power, you can calculate the efficiency and radiating resistance.

Assuming that the radiation resistance is in series with the loss
resistance, it would be enough to measure just the antenna current,
which also flows through the radiation resistance, producing the
already measured total radiated field.

You can't directly measure radiation resistance, because it's embedded in loss resistances and usually reactance too. Also there's more than one definition of radiation resistance: some would say that the radiation resistance of a half-wave dipole depends on where and how it is fed (centre, end, off-centre); while others would say that the radiation resistance stays the same, and it's only the feedpoint impedance that depends on the method of feed.

Since you can't measure it and there isn't even a universally agreed definition, it's best to tiptoe quietly away from "radiation resistance" before the Holy Wars begin...

What you can measure directly is impedance at the feedpoint. That is of much more practical interest. For that job, an R-X noise bridge is probably the minimum entry-level instrument.

In principle you could measure impedance using a sig gen and a two-channel scope, measuring the amplitude and phase difference across a series resistor feeding the unknown load. But in practice you wouldn't get very accurate results above MF, and it's a heap of equipment to carry outside where you'd want to use it.

'Antenna analysers' such as the MFJ-259B are deservedly popular because they will do R-X measurements with acceptable accuracy, and the whole thing can be battery-powered and held in one hand. I'm looking forward to making some outdoor antenna measurements using the new N2PK vector network analyser... but not today <brrrr!>

I'm simply trying to establish the radiation resistance of a non-ideal
antenna so I can reasonably match it to the output impedance of the
transmitter PA stage. The figure is likely to be very low, given that
this antenna is highly non-ideal. I'm not interested in plotting polar
patterns of the radiation distribution!

Radiation resistance should always be referred to a particular point in an aerial.

It is not of much use unless used to calculate radiating efficiency in conjunction with conductor and other loss resistances.

The problem is not how to measure it but how to distinguish it from the aerial loss resistance in series with it.

It is that fictional resistance which, if inserted in the aerial at that point, dissipates the same power as is radiated when the same aerial current flows.

Radiation resistance can also be considered to be uniformly distributed along an aerial wire. It can then be directly compared with wire loss resistance.

It so happens the uniformly distributed radiation resistance is exactly twice the radiation resistance of a 1/2-wave dipole when concentrated at its centre. So the uniformly distributed radiation resistance along a 1/2-wave dipole is about 140 ohms. It cannot be measured. It can be calculated from aerial dimensions. But best just to remember the approximate number 140. It does depend to small extent on wire diameter and 'end-effect'.

If the wire end-to-end resistance of a 40m, 14-gauge dipole is, say, 2.76 ohms then -

Aerial efficiency = 100 * 140 / (140 + 2.76) = 98.0 percent.

Which is very good, isn't it? It's equivalent to 1/68th of an S-unit which cannot be detected even by using a magnifying glass and the bloody needle stands still for long enough.

Which also serves to illustrate how VERY uncrtical are aerial impedance measurements.

==========

The input impedance of a 1/2-wave resonant dipole is about 70 ohms. But this may be at a considerable distance from the transmitter output terminals. What do you have in mind to put in between?

Then all you have to do is find the purely resistive load the transmitter would be most happy with. Almost certainly it will not correspond to an impedance match.

Isn't free speech a wonderful thing? I followed the Tek thread with interest and am wondering if the whiners actually:

1. Have a use for instruments of this caliber
2. Know how to use them properly

I have used Tektronix instruments for almost 30 years now, and don't know how I could have got along without them. Most of my work has been in commercial radio and television.

The manuals are written incredibly well, and I have received assistance from tech support on devices more than 25 years old. Try that with Hitachi, Leader or Phillips or Sony. And I could still get parts for them!

I reflect with fondness on repairing a device like a waveform monitor, more than 20 years old, and finding a small coil of silver solder on the chassis in a place that was designed for it, tucked neatly in its own "home." Tek has used silver solder for decades now...they have always known it makes a better solder joint...and they want their stuff to keep on working, 24/7 for years and years. So they put their money where their mouth is, and provide the end user with what they consider to be a lifetime supply (for that instrument) of the stuff.

And now I hear that they desroy their own equipment so they can sell more new stuff?! Baloney.

I think I am hearing from people who not only do not understand that "you get what you pay for," but have no use for the quality and accuracy of the products they are complaining about.

Merry Chirstmas and Happy Holidays to all.

Reg,
The OP is working with very non-ideal antennas, for which the radiation
resistance is probably only an ohm or two, and he wants to know if it's
0.5 ohms or 5 ohms, for obvious reasons. I don't suppose there is any
realistic way of measuring it, and modelling may be extremely difficult
if the antenna shape is not simple.

I've seen antenna evaluation does on 1:10 and 1:20 scale models, but we
don't know what frequencies the OP is using, so even that may not be
practicable, but if it is, one could work back from field strength
measurements to radiation resistance, with a big pad between the
transmitter and the antenna to 'soak up' the mismatch.

It's annoying, because the tx output Z I'm trying to match is (by a
strange coincidence) 140 ohms! So a folded dipole would be ideal, I
guess. However - and it's a big *however* - I can't use one. I'm stuck
with a telescopic whip and a ground plane the size of a box of Swan
Vestas. I imagine the radiation resistance of such a non-ideal antenna
is pretty low, but until someone can gimme a ballpark figure for it, I
can't even begin to think about how to go about matching it. :-(

Depending on frequency in use, could you do it experimentally?

The way I tune up antennas for ham bands is to hook up a mfj 249 and the tuner to the antenna, get a best fit with the 249 and then replace the 249 with the radio and fine tune from there. There always seems to be some small differance between the result from the mfj and the meter built into the tuner, and at full power I would rather trust the meter built into the tuner (a Millen transmatch jr).

You could build an L match with a tapped inductor and variable cap, then experiment with values until you get somewhere in the ballpark of being matched. From there it is is just small adjustments to get perfect matching.
thanks, John.

> Icom rigs of that series have a logic circuit that is running on a battery .

No, it does not. There is no battery in the IC-251/IC-551. (Hell,
these rigs were built before The Invention Of The Battery. HI!HI!)

On the back of the rig you'll find a slide switch just above the
fuse holder. Slide it to "OFF". As you guessed, there is an
small Always-On PS running -- when this switch is in the "ON" posn,
and it holds the memories across (front-of-the-rig) Power On/Power Off
cycles. My IC-551 exhibits the symptoms you describe. (My IC-251A
does not - yet.) As to why it doesn't work per factory spec's anymore --
my guess it's a combination of the small half-wave rectifier PS getting
ratty, plus the aging of the micro-processor (sic) chip, and the
number of direct hits by cosmic rays over the decades it's been in
service.

Since there are only 3 steenkin' memories in these rigs anyway, it's
No Big Loss to lose the memories. I simply leave both rigs on all the
time -- only unplugging them at times during ThunderStorm Season.
I use both rigs for weak signal SSB only. So, my memory "needs" are
trivial.

Hi,

For a whip, much shorter than a quarter wave against a poor
ground - who knows? However, you want a number?

So here's a number; 2 - j500 and it won't be too far wrong.

The name of the game in such a situation is "Suck-it and see."

Make an intelligent guess at what the impedance is likely to
be, rig up a far-field meter and adjust the tap/link/network
until it peaks. Then go out for a curry and maybe a drink or two
or...

Alternatively, buy an antenna book and RTFM :-)

Cheers - Joe

>sounds like a BLT .Do a google search you should find some info.

The Norcal BLT (which is what I believe you're referring to) is a Z-match type of tuner. It uses a single toroid to create a coupling link between the unbalanced input and the balanced output.

The BLT's toroid is wound with a single primary (having a single fixed tap), and a pair of secondaries for low- and high-impedance loads. It does _not_ have the sort of multiply-tapped-and-switched coil architecture that the original poster alluded to - these are usually used in unbalanced-configuration T and L tuners. The tuning is done with the two capacitors (a series input cap, and a cap which shunts the primary toroid winding), and via a DPDT switch to select the appropriate secondary winding.

I don't know whether the OP's components and kit were originally intended for a multiply-tapped-inductor T tuner, or for a Z-match such as the BLT, but it sounds likely that they could probably be adapted to either (possibly with the addition of a few extra junkbox components).

I built a Norcal BLT a few months ago, and I've been quite happy with it... it's a nice little QRP design especially when modded to support coax-fed unbalanced antennas (add one BNC jack and one SPST switch). The lack of multiple inductor taps and a tap-selection switch is a definite plus, convenience-wise. It seems to tune my tri-wire fan dipole to off-resonant frequencies just as effectively as my big QRO tuner (based on the Ultimate Transmatch design, according to the guy who built it).

Then you want to know the feedpoint impedance, not the radiation
resistance.

You can measure that with any of a variety of impedance-measuring
devices. You need to be careful to not disturb the antenna with your
measurement, and to properly couple the measurement device to the
feedpoint, taking into account the effect of the coupling on the
measurement. For example, like Wes said, if you measure it through a
length of feedline, you need to accout for the impedance
transformation performed by that line, or calibrate your measurements
at the end of that line.

You can generally get a fairly accurate number through a simulation of
the antenna, too.

Cheers,
Tom

>How could you possibly define it otherwise?

Bill, I can get down to first principles if necessary, but that isn't
necessary, is it?

INDUCTANCE doesn't change over frequency...even above the
"self-resonance" due to distributed capacity between windings.
That's very basic and applies up into the region where the
frequency is so high the whole "coil" structure starts behaving
like a distributed-constant conglomeration of equivalent parts.
But, that's a specialty area and far above any practical
application of home-made coils for RF.

Reactance is a function of frequency and inductance. The
reactance of an inductor DOES change over frequency. That's
also very basic. For _practical_ home-made coils, the only
major concern is the distributed capacity of the coil structure.
Distributed capacity is the _equivalent_ of a fixed, parallel
capacitor across the pure inductor part of the coil. That L
and C will determine the "self resonance" of the structure.

To find the distributed capacity of an inductor (the equivalent of
a fixed parallel capacity connected across the inductor), the
method described in the "Reference Data for Radio Engineers,"
fourth edition, 1956, ITT (aka "Green Bible"), chapter 10, pp 268-
269 can be used as follows:

Using a Q Meter or other instrument with a calibrated variable
capacitor, resonate the parallel L-C with the capacitor at two
frequencies exactly an octave apart (1:2 ratio). Take the
difference of the two variable capacitor resonating values as
"deltac." Let "freqsq" be the _square_ of the highest of the two

frequencies used. For uHy, pFd, and MHz:

L = (19,000) / (freqsq x deltac)

Inductance L is the "true" inductance of the coil, separated from the distributed capacity.

The constant of "19,000" is a simple approximation considering that 1956 was the age of slide rules and electromechanical four-function calculators. If the parallel resonating capacitor is well-calibrated, the "true inductance" formula works out well. If the parallel resonating capacitor is not calibrated, forget the whole thing; there are several C-meters on the market that can allow rather precise +/- 0.1 pFd resolution calibration if anyone is into home metrology.

Anyone wishing to play with simple algebra can figure out the formula from basic resonance equation at two frequencies exactly an octave apart. That will result in the true mathematical value of the constant given in the Green Bible. :-)

You're wearing rose-colored glasses. They absolutely do destroy older equipment via the trade-in "bounties" collected by resellers such as Tucker. This is no secret in the industry.

That doesn't make them evil, and it doesn't make them "suck", but it does (IMHO) demonstrate a lack of respect for the engineering ethos and tradition that made the company great, while taking perfectly good equipment out of the ham/hobbyist community forever.

You could divide the T&M equipment world into two categories: stuff like logic analyzers and signature analyzers that's pretty much doomed to obsolescence the minute the first pilot build rolls off the production line; and gear like oscilloscopes and spectrum analyzers that still serves its original purpose decades after it's out of production. HP, for instance, made a lot of great test equipment, but a lot of it fell into the first category and nobody misses it much. For most of its life, Tektronix focused on the second category: scopes, spectrum analyzers, video monitoring equipment. In this regard, Tek's main competition is themselves, which is a problem for them.

Whether I'm a hobbyist or a pro, I can (and do) use an old 2430A DSO and 2467 analog scope to do just about anything I could do with a new $6K TDS3034B. That means that it's not really in Tek's best interest to support their customers in their efforts to keep the old gear alive.

> I think I am hearing from people who not only do not understand that
> "you get what you pay for," but have no use for the quality and
> accuracy of the products they are complaining about.

If you actually read the thread, you'll see that folks aren't complaining about the *products* as much they are the company's support policies and decision-making strategies. Yes, it sucks that they no longer honor Howard Vollum's lifetime warranty on 535 power transformers. It sucks that I can't get a replacement U800 for my 2467. It sucks that they sold the chip foundry to a bottom-feeding IC company known for promising the moon and delivering press releases. But Tek is what it is. They still make good scopes, even if they aren't worthy of the kind of adoration from the engineering community that they used to enjoy. And their legal department is actually pretty enlightened when it comes to granting permission to reproduce out-of-print T&M manuals

and documents.

Isn't this where -- at least in the software arena -- the idea of maintenance contracts comes in? Granted, the average hobbyist is typically not going to buy into such a plan, but I would imagine most of Tek's sales are to companies that would be willing to pay, e.g., 10-30% of the original equipment cost per year for a guarantee that the equipment will be repaired free of charge if it breaks. The new equipment is so much software-based as well these days that Tek could also consider changing for software upgrades -- although personally I'm quite happy that TDS3000 software upgrades are free!

I am going to get myself a nice 2465B or perhaps a 2467 after finish school and find myself a Real Job again -- in a sense those scopes seem like the pinnacle of pure-analog scope development and even if they are only good to 400MHz, there'll continue to be plenty of designs that can be serviced by such scopes for years to come.

> It sucks that I can't get a replacement U800 for my 2467.

Ah, but wasn't someone mentioning that some third party is making compatible replacements? It was supposedly very expensive, but if one person can do it, surely others can as well -- and will, once there's some demand. Look at the old computers such as the Commodore 64 -- these days people enjoy not only completely emulating them in software (doesn't applies to scopes, obviously) but also building equivalent pieces of hardware in FPGAs (e.g., the Commodore One).

I can see from the way you have made your enquiry you havn't the foggiest idea about what you are trying to accomplish. Do you know the frequency? What transmitter power output do you have in mind - 10 milliwatts or 1KW? For starters forget all about folding anything - you've been reading the wrong books. However you now mention a short whip above a groundplane of unknown construction.

The input radiation resistance at the base of a very short vertical antenna, say less than 1/10th of a wavelength, is given by -

Rrad = Squareroot(20 * Height in metres / Wavelength in metres) ohms.

Rrad will be in the order of a few tenths of an ohm at 2 MHz but increases fast as the square of frequency.

In series with this radiation resistance is a high value of capacitative reactance which has to be tuned out somewhere by a lot of micro-henries. Best located at or near the antenna base.

For a very crude guess the input reactance will be in the order of -

Xin = -300 * Cotangent(Angle) ohms.

where Angle = 360 * Height / Wavelength degrees.

You will then have the task of winding the correct number of turns on a coil former, of your chosen length and diameter, to provide an inductance of similar value of reactance as presented by the whip. Download program SOLNOID3 for coil design.

In series with Rrad and Xin there will be a loss resistance due to the connection to the ground plane. If the ground plane is a vehicle then you can expect a loss resistance between 3 and 15 ohms. If the ground plane consists of a cigarette-pack size metal plate buried in your back yard then expect a ground loss resistance between 500 and 5,000 ohms.

Overall antenna input resistance is then Rin = Rrad + Rcoil + Rground.

If it is your intention to connect the antenna directly to the transmitter, or via a very, very, short length of coaxial line, then Rin is the resistance which has to be matched to your 150-ohm transmitter by using an L and C impedance matching network.

Frankly, it may be easier to redesign the transmitter to match the antenna ;o)

But you won't get very far without an impedance measuring device such as a borrowed, begged or stolen antenna analyser.

As I have no idea of the purpose of the transmitter + antenna I suggest you ask around for sombody who has already solved the problem and copy his.

It may be that a very short miniature centre-loaded dipole would do the job. It doesn't need a groundplane and can be driven via a 150-ohm balanced, twisted-pair line and, if needed at the transmitter end, a simple 150-ohm, 1-to-1 balun.

Download program MIDLOAD and amuse yourself. It also designs the loading coil. I KNOW it works. Been there - done that!

Shielded 2-wire cable is used to wire phonograph pickups. The wire
size is generally pretty small, like 32AWG +/-. Try places like MCM
Electronics.

I would question this statement. I've seen lots of older 'scopes
and other gear at the Tektronix company surplus store, mainly 7000 and
11000 series.

I would be curious to know how much really is destroyed, and how
much makes it into the store's inventory. Perhaps someone who actually
works for Tektronix could comment?

Had a question for open discussion

Is there available, can it be done to have an AM and/ and or FM transmitter that will broadcast over the entire AM and FM broadcast band at the same time. Or at least multiple stations. E.G.

From 88 - 108 at once or 88-98, then 98-108
Same on AM band.

It would have to be a low power to be able to be used on private property and limiy range to 300 mtrs

Can this be done, where can l buy it, or how do l make it

Told you it was a dousy of a question, whats your thoughts.

In addition to the recommended books, take a look at Tek's "XYZs of Oscilloscopes", http://www.tek.com/Measurement/fundamentals/scopes/literature/XYZs_of_Scopes_English.pdf. You can find other useful information by going to the Tek website, http://www.tektronix.com, and selecting Manuals, then Classroom & Lab Resources from the Resources group at the left.

Paul, it would be reeeeally helpful if you'd include enough info so we
could give you a ballpark figure. What wavelength (or frequency)?
How long is the antenna? How big is that box? (Will someone be
holding it during operation?) Yeah, someone did offer a ballpark
figure, but that depends a whole lot on what fraction of a wavelength
you have for your antenna and your ground plane. (Or perhaps the
posting in which you explained all that hasn't made it to this corner
of the universe.)

Cheers,
Tom

Perhaps you didn't see the earlier posts on the subject. The frequency
is 40Mhz (radio control band) and the tx output stage as it stands
puts out maximum power of 475mW with a 140 ohm resistor as load. I
only *need* 50mW ERP., however, so can stand to see quite a bit of
loss from an inefficient antenna. The antenna I will be using is a
telescopic whip - exactly the same set-up as you see with model
vehicle radio control transmitters- which is what it is, in fact.
It ain't rocket science.
Someone out there must know the radiation resistance of such a
telescopic whip (which has a ground plane of just around 16 square
inches contained within the remote control handset) and the best way
to couple it to a PA with a 140 ohm output impedance?

Not with a single transmitter. You could build a comb generator and
modulate it for AM, but the quality would be poor For FM you either need
separate transmitters, or modulate the signal and mix it with a separate
oscillator for each channel. The big question is why you would want to
do it.

Nah, given a wideband signal source and amplifier, there's conceptually no reason he couldn't broadcast on all stations simultaneously! I find it a novel idea, actually.

> The big question is why you would want to
> do it.

I suspect he's thinking of something like those 'talking houses' where you're supposed to tune your radio to a given station and get information on why you want to drop a quarter million bucks on a thousand square feet of your very own sometime in the next 20 minutes... except he doesn't want people to have to tune at all!

Slightly less evil would be emergency broadcasting type uses...

You could generate it at one channel in the middle of the band then sample it
at 200 kHz to create replica spectra at the 200 kHz spacing. Probably will
need to keep the sampling pulse relatively narrow to avoid too much sinc(x)
roll-off. Any amplifiers after that point would need to support the entire
bandwidth.

4118. Does A sub L vary?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-09 01:58:50 UTC
From: amdx <amdx@att.net>
Message-ID: <u%9Bb.418361$0v4.20280358@bgtnsc04-news.ops.worldnet.att.net>
Source record: 30434

Does the A sub L of a ferrite core change at very low signal levels?

Background; Years ago in an electronics class we measured a

5 Henry laminated iron core inductors. We drove it with a low

current 60 hz signal. The whole class came up with an answer of

around .75 Henry. This was a 5 Henry high current inductor.

After some head scratching and looking at B-H curves I decided

it measured low because of the slope of the curve. At low B fields

the curve is horizontal and as B goes up the curve moves more

vertical.

So I'm wondering if the transformers we wind for antennas are

working properly at small signal antenna levels. Is our primary

reactance really 4 times the source impedance at very low signal

levels?

Does the AsubL of a ferrite core change at very low signal levels?

Mike

Its not a simple matter of matching the transmitter to the radiation resistance. First a short antenna is going to have a capacitive reactance. You must add an equal amount of inductive reactance (a loading coil) in order to cancel the capacitive reactance and make the antenna resonant at the operating frequency. Then what the transmitter needs to match is the total load impedance of the antenna "system". The load impedance includes the radiation resistance plus the resistance of the loading inductance plus the ground losses. The hardest thing to get a handle on will be the ground losses. The physical size of the transmitter housing is a small portion of a wavelength and losses will change as you handle the unit.

Yes, I kinda figured it was something like that after discovering it would go goofy if I left the Memory switch on and turned off the radio. Maybe that's why the guy I bought from said he left it on all the time. Ah, the nuances of old radios (at least there are no glass vacuum transistors in the 251!)

;)

I didn't think they had a button cell battery in them (or else they wouldn't need no steenkin' switch on the back of the radio)...beins I'm getting lazy in old age, I'll leave it alone and use the "work-around"...

Thanks for the insight.

50 W stud mount Zeners used to be a standard product, but most
manufacturers dropped them about 20 years ago. I understand that they
were still available from someone for a long time, but they might be
completely unavailable by now.

> Also, would it be possible to string a few lower volt watt zeners
>together to come up with a close value to what is needed?

Sure, string 10 3.6V/5 W Zeners, that would work fine if you can get
3.6V, which seems unlikely.

A more reasonable solution would be to make your own regulator using a
low power Zener and a power transistor that can handle the power. You
can make either a shunt or series regulator this way.

NO! In the above equation, X varies when F varies. The equation
does NOT mean that L varies as F varies.

The formula is fine. Your understanding of it is wrong.
X is inductive reactance.
F is frequency.
L is inductance.

F is a variable, L is fixed and X (the reactance of L at
the frequency) varies as the frequency varies.

Use a loading coil to resonate the antenna to 40MHz. Use a transformer
or tank circuit to transform the impedance.

You have had quite a few answers which seem pretty good to me.

I have a few comments.

Stop saying "radiation resistance" and start saying "input impedance" or "feed impedance." Once you know the input impedance, getting maximum power transfer is a straightforward matching problem that can be solved in a variety of ways. True, you won't know for sure how much power is "getting out," but some of the posts in this thread have given you some estimates. If that isn't good enough, then you will have to measure by putting a receive antenna in the far field.

Anyway, if you want to measure the input impedance, you should be able to do it with a two-channel oscilloscope and a 40 MHz function generator. Drive the antenna with the function generator and simultaneously measure the input voltage and current, including the phase relationship between them. The input impedance is V/I. To measure the current, put a suitably sized resistor in series with the antenna and measure the voltage across it. The voltage across the resistor should be small compared to the voltage into the antenna. If it is too small to see, use a bigger resistor

until you can see it. Make sure both oscilloscope probes are grounded in the same place. Unless you have a differential probe (in which case, use it to measure the voltage across the current sensing resistor).

From what others have already said, it sounds like the input will be extremely capacitive with a small series resistance. Once you know the details, however, it will be easy to tell you how to match this to your amplifier.

That's my $0.02.

Mac

That is what everybody is trying to say.

It is like discussing is a candle _emitting_light_ into the room or is
the candle _absorbing_darkness_. This becomes quite apparent when the
wick of the candle is black when the candle has been put out, clearly
it has absorbed a lot of darkness :-).

In an incandescent lamp, the electric current will constantly renew
the filament, thus preventing a lot of darkness being concentrated on
the filament.

One could develop quite scientific methods to measure the amount of
darkness absorbed and predict the behaviour of other lamps. This can
also be debated successfully for a quite a while, until some serious
disagreeing measurements are brought into the discussion.

>The disagreement here seems to depend on how one defines what inductance
>is.

It has often been defined by the ability to store energy.

>I maintain that inductance of a coil is nothing more than the
>reactance divided by 2piF, as derived from the formula above.

L = Xl / (2 pi f) applies only to _pure_inductive Xl

It does _not_ apply to L = X / (2 pi f) in which X is some combination
of Xl and Xc !

>Do you disagree with that?

>That formula has been taught for decades. Are you saying it is wrong?

The formulas taught for decades are:

Xl = 2 pi f L _and _ Xc = -1/(2 pi f C)

How do you arrive to the incorrect L = X / (2 pi f) from the
equations above ?

Please note, it is the magnitude of X what you are measuring with some
simple test gear, not Xl. Thus, the original claim is an artefact of
the measurement method.

Paul, standard CB antennas are loaded whips, for operation
at around 30MHz. Available in the CPC catalogue for about
ï¿½10 to ï¿½20, Perhaps you could start off with one of those
and modify to suit.

Note also that there is a 433MHz licence-free band for
short distance (100m) remote control. Pre-built Tx and
Rx modules are cheap, and a 433MHz antenna would be a
breeze.

Source record: 30445

How small?
How much?
How fast?
How cheap?

Go to the nearest garage sale and pick up a couple of sets of
headphones...
Walkman one-piece style with a single wire going into one earpiece, with
another going over the headband to the other earpiece. Get out the
ol'
cutters and snip off the connector and headphones and you have in your
hand, a
piece of two conductor shielded cable!
It's pretty small diameter, and has small conductors, but not near as
small as
the cable used to wire up phono cartridges....
Another source is radio shack. Go in and buy a headphone extension
cable with
mini-plug and jack, then cut off the ends. You can get these up to 15
feet
long (or so), but the cost per foot is higher than the garage sale
route....
(but at least it's new cable). They also used to sell a stereo
headphone
that was for listening to your tv, and the cord was about 25 feet
long...
pretty inexpensive at the time too, at least it was cheaper than an
equivalent
length of their "extension" cables... Of course these day, you'd
probably be
lucky to find even the stereo headphone extension cable if your
rat-shack is
anything like the one near me...

If you need large quantities of this sort of stuff, you should be able
to get
it from any of a number of commercial wire distributors. Think
mini-audio
wire and you'll be in the right section.

Hello all

I can scavenge components from junked motherboards - most are fairly easy to id. EXCEPT: Many of the boards have small "donut" ferrites pianted light green all over with one "sidewall" blue. They are all located in the power supply/regulation section of the m/boards. most boards have only one but occasionally there are 2 of them.

Are these any good for RF use or should they go into the trash?

That's right. You end up with X/2piF and X and F are inter-related;
they are not independent variables.

Apparently someone believes it's possible as an application was recently
filed with the FCC for an experimental license to operate just such a
system across the FM band. (the Commission denied the application)

Their intent was to install transmitters on emergency vehicles, so they
could warn other motorists to get out of the way.

My guess is the FCC feared these devices would "get out into the wild" -
can you imagine what an unscrupulous nightclub owner (or someone with
a political bone to pick) could do with a few of these?

Hi !

I have a copy of the lecture Matjas held here in Germany at the Weinheim
VHF Meeting 1998

He discribes several VCO from 2...4Ghz with BB833 and BB857.
and the block diagram of a spectrum analyzer.

I also did some work on that moving the range up to 3...5,3GHz for
use as doubled 10GHz Transmitter for high speed packet radio.

Best regards

Volker, DF7IT/WT0K, Weinheim, Germany

It depends on what they were doing on that motherboard. If they were
part of an RF interference filter, they may have other RF uses. If
they were the energy storage inductor in a switching regulator, they
may have their best performance under 1 MHz. You might look up some
of the common color codes and standard core sizes, and measure the
inductance and calculate the permeability of your cores to see if they
match any of the code specs. This could help to nail down the useful
frequency range.

This needs clarification. Do you mean that it will generate multiple
carriers? Like this?

At the same time the output has carriers @ 88.1 and 88.3 and 88.5 and
88.7.....97.5 and 97.7 and 97.9 ????

Actually this is possible if you
can make the proper circuitry. An oscillator FM modulated with a 200 KHz
signal will do it. You just need enough deviation. You could also add in
the audio modulation.

Forgot to mention that I've done it.

1) you guys are just arguing symantics. You both know what really happens.
".... "Inductance" vs. the total reactance measuring as inductive...." call
it what you like.

1a)
You are also both using (some might say mis-using) the term "linear" to mean
"varies linearly with..." rather than the more common meaning that
superposition applies. RLC sircuits are linear. Any given parameter may
not vary linearly as the frequency is varied. Also, this use of 'linear'
depends upon the type of scale being used--log or linear.

2) John,
You better re-think your last statement about the series equivalent of a
practical coil. It implies that there is some way to measure a low Z at the
resonance of the coil under discussion. You say:
"The series
> equivalent [impedance ? Steve] goes down as the frequency increases,
and goes to zero at
> resonance. "
While a series resonant LC exhibits this behavior, the series equivalent
of a practical coil does not do this. The series equivalent must do the
same thing as the parallel equivalent -- namely go to a high impedance at
resonance. That's why it is called *equivalent*--the total, or terminal
impedance is equal for the two representations (at a single frequency).

Pretty sure I got that right....
Steve
k]9]d]c]i

A practical coil usually goes to parallel resonance - at which the series
equivalent does not go to zero

Not sure why this one is elluding me, but , I have a graphics display with an led backlight drawing about 450ma @ 5v. While a large 7805 is rated for an amp it's getting pretty hot even with a nice sized heat sink.

Any thoughts on another way to drive this backlight? I was thinking of running it at 12v (it's going in a radio) and a dropping resistor. What say?

Gents,

Another practical consideration. Another area where caution is
advised--paralleling bypass caps. In solid state Power Amplifier design,
such a configuratin can cause problems because there is a point where one is
above self resonance and acts like an inductance in parallel with the other
cap which is still capacitive-- thus, resonance and no bypass. Been there,
done that. We put a small Z in between. Frequently a small bead or
resistor if possible.
Seems there is an equivalent problem with series inductors.

Use both every day. The digital scope (Tek DPO style) is great for analysing,
but sometimes is it a lot easier to find a problem on the old 500MHz 7904.
Once I find the problem signal, I can then set the digital scope to trigger
properly and analyse the details.

The 7904 is the "stand" for the 3054.

Steve.

OOPS Bill. By the formula, change F and Xl changes! Avery said below;
"reactance changes with frequency" and is correct. Also, if you change L
then Xl changes, but that is not what he said.

> Not sure why this one is elluding me, but , I have a graphics display with
> an led backlight drawing about 450ma @ 5v. While a large 7805 is rated for
> an amp it's getting pretty hot even with a nice sized heat sink.

What voltage are you feeding IN to the 7805?

Example: Say you feed 20VDC to the input. That means the regulator
gets to waste 15V of that as heat. Although current in a series circuit
is constant, one must take into account the current used by the
regulator itself to operate. So, in addition to your 450mA for the
backlight, you're going to be drawing up to 8mA more for the regulator.

Given (Ohm's Law) P=IE: You have up to 458mA times 15V giving 6.87
watts worth of power dissipated as heat. That's a lot of heat, so yes,
your regulator getting warm is very normal. It gets worse when the input
voltage goes up, or when the current draw increases.

The 7805 was a fine part in its time, but there are other more
modern (switching) regulators that do a much more efficient job.
Although implementing such may take a few more parts, I would look
seriously at using something from, say, Linear Technology.

> Any thoughts on another way to drive this backlight? I was thinking of
> running it at 12v (it's going in a radio) and a dropping resistor. What say?

Even worse. You'll need a plenty big power resistor, it'll waste a
lot of power as heat, and you'll have practically no immunity from
spikes and surges. Try the switching regulator idea first.

Ahhhh! So there does seem to be a mis interpretation of the formula
here.-Steve

Bill,
I believe you are placing the dependant and independent variables in the
wrong place. The Xl is the dependant variable. Xl *depends upon* F and L,
not the other way around. That is, given an L and F you calculate the X.
X is the answer.
Only if you know there are no other contributing factors can the formula
be used the other way, because it does not factor them (the parasitic
capacitance) in. That is, Given an X measurement you can not tell the
inductance, only the *equivalent total* inductive reactance.

I don't quite follow where you are going here. below the self resonant
freq the angle will be +90 (minus a little for what ever resistance is
there).

The rest of this about measuring the energy from DC, I don't think is at all
practical.

Yes, this is good advice.
Actually I have been getting QST since I passed my Ham exam a few month ago
but had not really started reading it seriously (now that I am semi snowed
in it will be a great read).
But you are right, the hints and kinks section and in particular the
apparently rather new "Hands-on radio" section are quite useful.
Maybe I was concentrating too much on the scope, but if I just patiently
read QST for a while I will probably get all the info I ever wanted.

Best regards from Maine

Hi,

I'm currently working on this VCXO that achieves frequency shift by
applying DC bias to two varactor diodes connected cathode to cathode
(bias applied to the junction between them). If I can't get enough
shift with the available bias voltage, is there any problem with just
putting another pair of the same diodes in parallel with the existing
ones?
This is a ceramic resonator oscillator, BTW, so will stand a lot more
'pulling' than a xtal would, so don't worry about that aspect of it.

>
> --
> Bill, W6WRT

The inductance is not changing. What you are measuring is not pure inductance but the coil has a stray capacitance. That is what is making the coil seof resonate.

YOu did not say what hapens at 110 mhz, 200 mhz, and 500 mhz, if you did , it would measuer capacitance reactance. How do you change a coil into a capacitor ? You don't , but the effect of reactance has.

Look at it this from a totally differant angle. You stick the leads of a DV voltmeter in the wall socket. It does not show any deflection other than maybe the first jump when it is plugged in. Does that mean there is no voltage or power in the circuit, I think not. Stick your fingers in it and see what hapens :-)

Your method is flawed in the same way, you only measured inductance (not really that , but the inductive reactance at a given frequency, but did not measuer capcitance. Where did the capacitance come from ? It is what makes the coil selfresonante. If you measuer a circuit that has inductance, capacitance and resistance, depending on if it is series or pareallel resonate here is what will hapen. As the frequency is increaced the inductance reactance will increace, it will measuer resistance at the reosnant frequency , then a large capacitance reactance and then a small capacitance reactance or else the reverse will hapen, capacitive reactance, resisstance, inductive reactance. However none of the actual inductance, capacitance or resistance values will change. YOu are confusing inductacne and reactance.

YOu are only seeing one part of the big picture. YOu have to look at several formulars to see what is going on in a circuit that has inductance and capacitance.

Paul,
The amount of tuning range is a function of the ratio of Cmax/Cmin. If you parallel varactors, Cmax will double, but so will Cmin. The ratio hasn't changed.

If you're not already using a "hyper-abrupt" type of varactor, you should look into one. They offer a wider capacitance range.

What type of varactor are you using, and what's the frequency of the resonator? What's the application...linear frequency modulation like FM or data keying like FSK???

Joe

>saying it is wrong?

I'm saying that the student doesn't understand inductance.

Inductance does NOT vary over frequency for any coil of wire under
its self-resonance.

Reactance varies over frequency with inductance fixed...directly
proportional to frequency. Inductance doesn't vary.

Yes, you can FIND inductance in Henries if you measure its
reactance at a particular frequency. Inductance in Henries has NOT
changed by doing so. Inductance in Henries remains constant.

[feel free to quibble over the spelling of "Henries" v. "Henrys" :-)]

If your reactance-measuring gizmo is not calibrated properly, then
its readings will show an APPARENT change in inductance. The
inductance still hasn't changed...only the calibration of the gizmo
is off.

Don't get all wound up and take a turn for the worse...

Paul, That will work, but will double *both* min and max capacitance.
But I'm puzzled: "I can't get enough shift with the available bias
voltage" implies you're on the *low* end of capacitance (highest
voltage).

Source record: 30365

OK, here's a challenge to you guys ... I have been trying to ID a IC / inductor combination to generate 150 to 200 VDC ... in the nano-microamp range. I need to supply a bias voltage to an electrostatic microphone element.

Any ideas ??

Wish list:

Very low current ... < 2ma ;-)
Runs from 5 to 9 volt DC source
Minimal components

Most of the specs I find for HV units (backlight supplies) are too much current. Most of the inductor type DC-DC converters seem geared towards low voltage high current apps.

Will watch the discussion for tips and ideas ... all welcome.

Thanks

Tony, KD7TOG

Here are your own words:
"At that self-resonant frequency, the coil is behaving like a
parallel resonant circuit, which of course it is, due to the
parasitic capacitance between each winding."

Your example ignores the capacitance, which you have stated
exists. There is nothing in your formula that addresses it.

You cannot use the formula or the math above (in your post) to
support your point of view, because it does not contain any
term for capacitance. The capacitance exists, and exhibits
a larger and larger affect on the circuit as the frequency
increases from 1 -> 99 mHz.

Sure. Is this a coaxial ceramic resonator, or one of the low-freq
piezo things? What's the frequency, Kenneth? [1]

Program models TRUE measurements of SWR and Rho by moving current and
voltage probes along a transmission line.

Exact classical transmission line formulae used on a real lossy line with a
complex value of Zo = Ro - jXo.

Covers frequencies 20 Hz to 1GHz.

Download from website below program RHO_SWR, 50 kilobytes in a few seconds.

Read introductory notes.

While I agree with much of what you say, it's only fair to point out that it's the old-timers among us who mostly feel this way. Tek has changed.

>The manuals are written incredibly well, and I have received
>assistance from tech support on devices more than 25 years old.

Yes, the OLD manuals were wonderful, but have you looked at a manual for a Tek scope sold new in the last 10 years? They have no theory of operation, no parts lists, and no schematics. If you try to call them for tech info on an old scope today, you're pretty likely to be politely turned down.

>I reflect with fondness on repairing a device like a waveform monitor,
>more than 20 years old, and finding a small coil of silver solder on
>the chassis in a place that was designed for it, tucked neatly in its
>own "home." Tek has used silver solder for decades now...they have
>always known it makes a better solder joint...and they want their
>stuff to keep on working, 24/7 for years and years.

The special little coils of silver bearing solder WERE neat, but they were intended for use ONLY on the little ceramic terminal strips. The silver content was necessary to prevent delamination of the metalized part of the strip. This was carefully explained in their manual.

I don't think they used that solder in any solid state gear, nor did they provide the little rolls in any solid state scopes.

>And now I hear that they desroy their own equipment so they can sell
>more new stuff?! Baloney.

Baloney perhaps, but I belive it is still true. I've heard it from people who were there and saw it happen.

>I think I am hearing from people who not only do not understand that
>"you get what you pay for," but have no use for the quality and
>accuracy of the products they are complaining about.

The scopes you're remembering are the products made decades ago. Those were the scopes that made Tektronix' reputation as exceeding the "state of the art." In recent times Tek has been taken over by the bean counters who have entirely different priorities.

It's unfortunate that a giant like this has now stooped to this level, but you really should listen to some of the people here, and elsewhere, who have worked with them, and for them, in recent times.

I'm afraid that much the same thing is happening to Hewlett-Packard. The corporate climate that Bill Hewlett and David Packard spent their lives building has now gone the way of corporate acquisition over innovation. Agilent may continue to do well, but Bill & Dave's names have been sacrificed on the alter of profit.

Yes, I own several old Tek scopes. I consider myself a Tek youngster as I've only been using them for about 35 years. I've got a nice new one at work that only seems to weigh a couple of pounds and still does 300MHz. It takes me 20 minutes to figure it out every time I turn it on, but I assume that's just because I don't turn it on frequently enough.

Nothing is likely to be very efficient at this low power level. I
think I would look into a step up transformer design, perhaps using
something like a MT4143:
http://www.tamuracorp.com/pdf/MET-01.pdf
driven by a two transistor half bridge at ultrasonic frequency. With
a 14 to 1 step up, it could produce 200 volts peak across the whole
secondary, with only 7 volts peak across half its primary. If the
secondary was connected to a voltage doubler, you could drive it with
half that. The transformer is rated for 10 mw, but at 20 kHz, I think
it could do a bit more than that or run fairly efficiently at much
less.

>How can it be otherwise?

As Spock said to Kirk, "You proceed from a false assumption." Or, to
put it another way, the scenario you've just laid out contains an
inherent contradiction.

The inductance meter that you are using (or assuming) is not actually
measuring inductance. It's measuring reactance, and back-calculating
to what the inductance would be *if* it were measuring a "pure"
inductance.

However, as you recognize, the component that you are measuring is
not a pure inductance. Its actual reactance is the result of
interaction between its inductance, its inter-winding and distributed
capacitance, and its winding resistance (at any given frequency).

So, what you're observing can best be interpreted as follows:

- At low frequencies (well below resonance), the component's reactance is dominated by its inductive component. It's a decent approximation of a "pure" inductance. The inductance meter gives accurate estimate of the inductive component.

- At high frequencies (well above resonance), the component's reactance is dominated by its capacitive component. It becomes a decent approximation of a "pure" capacitance at some point, I suspect.

At these frequencies, your simple inductance meter lies through its teeth. It "tells" you that the part's inductance is such-and-such, but it's not telling you the truth. It's hiding from you the fact that the reactance it's seeing isn't inductive at all (the reactance decreases as frequency goes up, and exhibits a capacitive phase angle).

So, I think, what you're facing here is the problem which occurs when you try to force simplifying assumptions ("the component being measured is a pure inductance" and "an inductance meter actually measures inductance") outside the range in which these assumptions are valid.

>
> 1. What is its reactance?
> 2. What is its inductance?

Its impedance has been measured to have a magnitude of 50,000 ohms.
If you have independent information that its Q is very high, you can
assume that this impedance is made up of some combination of inductive
reactance and capacitive reactance. With a single measurement such as
this, that is about all you can say.

It cannot be assumed to be all inductive reactance (or any particular
combination of inductive and capacitive reactances), just because
someone labeled the device as an inductor or because it looks like a
coil. Other measurements are needed to nail the details.

A parallel resonance with 50,000 ohms impedance (at some frequency) is
not the same thing as an inductance with 50,000 ohms of inductive
reactance (at the same frequency). They pass a similar magnitude of
current at that frequency for the same applied AC, but their current
phases do not match. And their reaction to nonsinusiodal waveforms is
very different.

>
>Suppose you have a coil which measures 1 uH at 1 MHz. It is known to
>have a self-resonant (parallel) frequency of 100 MHz.

OK, it has a distributed capacity of 2.533 pFd.

The circuit being measured is composed of a pure inductance
of 1.000 uHy and pure capacitance of 2.533 pFd in parallel.

We can neglect the losses in each one of those components
for the sake of illustration.

>You measure its reactance at 1 MHz using the formula X=2*pi*F and find
>it to be 6.28 ohms.

The inductive reactance is 6.28319 Ohms at 1 MHz and the
capacitive reactance is 62.8326 KOhms at 1 MHz.

In terms of susceptance, the B_sub_L is 0.159153 and
15.9153x10^-6 mhos, respectively. Total susceptance is then
0.159137 mhos or 6.28389 Ohms. [reactance meter probably isn't
calibrated that close to show the slight change due to distributed
capacity]

>At 2 MHz you find it to be 12.56 ohms.

At 2 MHz, the inductive reactance is 12.5664 Ohms or 0.0795775
mhos while the distributed capacitance has 31.8306 mhos. The
total susceptance is 0.0795456 mhos or 12.5714 Ohms. That is
within 0.0907% of 12.56 Ohms and darn few reactance measuring
gizmos are calibrated that close...

>At 10 MHz you find it to be 62.8 ohms.

Okay, at 10 MHz, the inductive susceptance is 0.0159155 mhos
and the capacitive susceptance is 159.153 x 10^-6 mhos, the
total being 0.0157563 mhos or 63.4665 Ohms reactance. That's
an error of 1.061% from 62.8 and still fairly reasonable for the error
of a reactance meter or whatever.

>So far the reactance is changing linearly with respect to frequency.
>(Actually it is not perfectly linear, but the difference at these
>frequencies is small and probably would not be observed with run of the
>mill test equipment.)

Okay, that's progress. We are agreed that test equipment can have
errors...he said with a grin having worked in metrology and a
standards lab for over 2 years in the past... :-)

>But, as you approach 100 MHz, you find the change is obviously no longer
>linear.

Ah, but you are measuring TWO things at the same time, the
parallel of the true inductor and its distributed capacity. Once you
are into measuring multiple elements, you need a test setup to
try to get a handle on the individual components. That is why I
brought up the "true inductance" two-frequency test on a Q meter
that has a calibrated tuning capacitor. That WILL establish the
equivalent pure capacitor due to distributed winding capacity in the
coil (the physical inductor form).

Once you KNOW the distributed capacity, its just a matter of some
button-pushing on a good scientific handheld calculator to derive
true inductance from the reactance readings of both inductance and
distributed capacity. [I recommend an HP 32 S II as an RPN fan]

The parallel capacitance will definitely exist as more picoFarads in
a circuit such as a FET gate which has a very high parallel resistance
(or very low conductance if you can think in terms of admittance).
That FET input capacitance will change the higher frequency resonance
even lower.

Offhand, I'd say that 2.533 pFd distributed capacity is rather high and
probably is around 1.0 pFd (solenoidal type, no core)...but a FET
gate input and its PCB traces to ground plane can be an additional
2.0 pFd. That's 3.0 pFd total and the self-resonance of that circuit is
now 91.888 MHz.

>This is not an illusion. If you have an inductance meter which uses 99
>MHz as a test frequency, it WILL MEASURE 80.4 uH.

That "inductance meter" is still measuring TWO THINGS AT THE
SAME TIME. The physical coil still has two components, the
pure inductance in parallel with a pure capacitance representing
the distributed capacity of the windings. Those are inseperable
unless you do something like the "true inductance" test at octave
separation frequencies or equivalent.

A Q Meter of any kind made today, last year, or back in the pre-history before 1947, MEASURES THREE THINGS AT THE SAME TIME! Yet the Q Meter is still accurate enough to derive the equivalent parallel resistance, parallel inductance, and parallel capacitance of the physical coil's windings. [it actually measures conductance and susceptance as a total magnitude and relates that to the Q or loss factor while the calibrated frequency setting and calibrated variable capacitor allow separate "inductance" measurement even though the Q Meter is "looking" at both L and C_sub_d in parallel]

ANYONE using test equipment SHOULD be aware of what their equipment does, how it works (in general), and what it really measures. Since inductance does NOT change in a passive coil (that isn't otherwise influenced by magnetic fields), what anyone measures on a particular coil is THREE THINGS: The conductance due to losses and the susceptance due to BOTH parallel inductance and parallel capacitance. Conductance will change with frequency depending on a lot of different factors (coil form, coil core, wire used, shield used (if any), dielectric of the former material, core permittivity, etc.). Susceptance will change with frequency because of the TWO components...BUT THE INDUCTIVE COMPONENT DOES NOT CHANGE.

>And therefore, I maintain that inductance DOES vary with frequency.
>
>How can it be otherwise?

The baseline taught in all textbooks (where I learned it first) and in classes (where I learned it second) all agree that one MUST separate the components into their "pure" form and THEN derive the component parts by different tests. That is how it is perceived by most other folks based on a lot of first-principle demonstration.

Inductance of a coil DOES NOT CHANGE WITH FREQUENCY.
Basic definition. First-principle stuff by definition.

You CAN say that APPARENT inductance changes if you are just doing one kind of test. "Apparent" isn't going to work well when this coil is dropped into a circuit thinking that "inductance changes with frequency" and the circuit contains a lot of other sneaky little components that can shoot the "apparent" reading way off. No one successfully works with L-C and active-device networks using this "apparent" reading. One separates the component parts first, then combines them into manageable parallel-equivalent or series-equivalent circuits.

The ILLUSION is from looking at an impedance- or admittance-measuring instrument such as a Q Meter and thinking its calibrated inductance dial "measures inductance." It doesn't...but it comes very close. That is just the calibrated variable capacitor tuning to resonance at specific frequencies...as a convenience to the user. The capacitance markings will be accurate but any external coil that has significant parallel

capacitance from its windings will add to the calibrated capacity on the dial. Some Q Meters allow variable frequency settings to do things like the octave-separation-of-frequency measurement of the external test parallel capacity.

An impedance or admittance bridge type of instrument can yield different "errors" and "illusions" depending on their type/kind.

Tony,

To make it easy snag one of the surplus electronic flash units or
dismantle a disposable camera. Some of them are quite small.
An RC filter will clean up the DC and a simple resistor voltage
divider to cut the voltage to what you want. Regulation shouldn't be
a problem with a steady and low current draw.

To get the input current down it may help to swap the photoiflash
capacitor for something with very low leakage.

73,
Jim

There's another reason.

For a long time, scopes were designed by engineers who used scopes daily, as their main tool. It wasn't any trick at all for them to select features that were useful, and operation that was intuitive. These days, the features are decided mainly by marketers and upper level managers, few of whom ever spent any time actually using a scope. They're implemented by software engineers, most of whom don't have the slightest idea what a scope does or how to use one. Consequently, we can look forward to a future of instruments that will be harder and harder to use and understand, and won't have the feature set the user really needs.

I'll give you just one example, from the development of one of the first highly digital lines of scopes. A mock-up had been created out of some computer pieces, a display unit, and bits of this and that, so the engineers could get a sense of how the new instrument was to use. I sat down at the bench, and the first thing I did was to adjust the horizontal position. I turned the (only) knob clockwise, and the trace moved to the left. "Oh," I said to the software engineer who had implemented most of the functions, "I see you've got that backward, but that's easy enough to fix." "No," he said, "that's how I intended it to work. It's logical: the delay increases when you turn the knob clockwise." Pointing out to him that, logical or not, it would throw a barrier in the way of every person who ever used the instrument, had absolutely no effect on his certainty that his way was best(*). (And, yes, I would have made the exact same argument that turning the knob to the right *should* move the display to the left if the instrument were a spectrum analyzer.) In this case, the project manager was a former analog engineer, and he overruled the software engineer. But these days, most management positions are filled with people who have seldom or never actually used a scope, so more and more counter-intuitive, clumsy,

and useless features are showing up. Get used to it.

(*) In the '60's, when I was a technician, every place I went would have a bunch of Tek scopes and one or two HPs. The HPs were just fine, except that HP had insisted on making their own user interface. Where a Tek scope would use a knob, they'd use buttons, and so forth, and the controls were all put in different spots. We'd swear if we got stuck with using one of the HPs, since it would take so long to figure out where the needed control was and which way to turn it or which button to push. So no one ever recommended buying an HP -- we all wanted Tek scopes -- and as much due to familiarity as anything else. Then the Japanese scopes came on the market. Y'know what? The knobs and other controls were not only in exactly the same places as on Tek scopes, they were even the same shape and color. We could pick one up and begin using it right away. Y'know what else? Tek took a real beating from the Japanese scopes, way worse than they ever did from HP.

A simple low-RF oscillator can do it with a small transformer having
an enormous turns ratio. I'd suggest a toroidal type with a ferrite
core rather than powdered-iron core to work around 50 to 100 KHz.
Something like a 1:30 turns ratio seems about right with the
secondary tuned, the primary driven by a single transistor emitter,
feedback to the base which will also load down the tuned secondary
some. Maybe a Darlington connection using two bipolars if too
much resistive loading.

Since a 2.5 mHy 4-pie RFC and 1000 pFd tune very close to 100 KHz,
you might use that as the "secondary." The "primary" could have
several turns wound in between the pie sections. Bulkier than a
toroid but a lot easier to handle on the first go-around for feasibility
checking. With 3900 pFd, the 2.5 mHy RFC will tune about 51 KHz.

Staying in the LF region allows most ordinary newer silicon diodes
to directly rectify the LF yet the harmonics don't interfere much with
AM radios nearby. It's well above the top frequency for human
hearing so a simple C-R-C filter ought to make the DC fairly clean
for the microphone without too much C value and bulk.

> Bill, W6WRT

I am not tap dancing around that formula. To be a self-resonance , the coil must have some capacitance somewhere. You are leaving that out by just using one formula. You also have to use the Xc=/(2pi*f*C) to get the capacitance and then to find the final results you have to use Xo=Xl-Xc.

As to what you are asking for , it could be almost anything for the inductance. It all depends on the stray capacitance. ?Remember you into this self resonance so there has to be some capacitance. There is an infinante number of solutions to the inductance of this problem.

The simple circuits that are most often found to measuer inductance do not take the capacitance that may be there into concideration.

Just as if you are using a simple SWR meter and have a SWR of 2:1. You do not know if you have a 25 ohm resistor or a 100 ohm resistor hooked to it. Either will show 2:1. Also if there is any reactance , either inductive or capacitive the simple SWR meter will not show that either. Again there is an infiniante number of capacitors and inductor and resistors that will show up as a 2:1 swr. You need a beter instrument.

4170. Re: Max nr of poles in CW-filter ?

I missed most of this thread, so this might already have been covered.

When making a filter for CW, it's essential that you pay careful attenuation to the time-domain response, and don't concentrate exclusively on the frequency domain. Otherwise, you're apt to end up with a filter that rings badly, and makes it difficult or impossible to copy CW. If you're a very slow speed operator, you can put up with more ringing, but at higher speeds, good transient response is vital.

Among the canonical filter types, I've found the Butterworth to be a very good compromise for CW. It provides tolerable transient response while having a respectable rolloff characteristic. In practice, a more optimum design (i.e., equal sharpness and transient response with fewer total poles) can often or always be realized with a combination of a sharper filter type like a Chebyshev or even elliptical, with added allpass poles to correct the phase response and therefore tame the ringing. However, the latter approach can be a good deal more time consuming -- you can look up the pole locations for a Butterworth in a table, synthesize the filter, and have a reasonable expectation that it'll work pretty much as designed. On the other hand, a phase-corrected Chebyshev or elliptical filter can involve a lot of trial and error modeling.

It's likely that they'd be ok for making RF chokes, broadband transformers, and baluns, and for EMI suppression, and that they wouldn't be suitable for use as inductors in tuned circuits, oscillator tanks, or anywhere that Q or temperature sensitivity are a factor.

You can put one or more turns on a core and measure its impedance (R and X) by a number of means -- signal generator and scope, impedance bridge, or antenna analyzer. For the applications I listed they'd be likely to be suitable for, you want the highest impedance per turn squared possible -- it doesn't matter whether it's R or X unless you're dealing with a lot of power. For tuned circuit inductors, you need high Q, that is, high series X/R ratio.

>
>____
>
>And what is the basis for the second statement above? Network analysis
>normally combines reactances of opposite signs and treats them as a
>single reactance, provided the frequency is constant of course.

Yes, that is true.

For a series resonant circuit X = Xl + Xc and since Xl and Xc have
opposite signs, the total reactance is less than either of them. At
resonance, their magnitude is the same and they cancel each other,
thus, the reactance is zero at resonance.

The situation is a bit more complicated with parallel resonant
circuits (hopefully I got the formula right)

X = 1 / (1 / Xl + 1 / Xc)

At resonance 1/Xl and 1/Xc have equal magnitude but opposite sign and
the divisor goes to zero and X to infinity. At resonance X also
changes sign.

Most test equipment simply measure the total reactance
X = 1 / (1 / Xl + 1 / Xc) at a specified frequency f.

Using the notations

Xl = 2 pi f L
Xc = -1/(2 pi f C)

Please show _mathematically_ how you from a single measurement of the
total reactance X at frequency f can solve both the inductance L and
capacitance C.

If you can not do it, then the single measurement of the total
reactance X is not sufficient for solving both L and C :-).

You could also start with the simpler series resonance (X = Xl + Xc)
case in which the measured reactance X is the end to end reactance.

And please, do not try to invent your own formulas such as
L = X / (2 pi f) when the components of X are unknown. That formula
is only valid in a special case when X is known to be a pure inductive
reactance Xl.

> Are these any good for RF use or should they go into the trash?

Motherboards and other circuits have some/many pass-through ferrite beads which I find very useful to recycle as RF-block inductors in my circuits.

In dead-bug construction style the use of these beads is very easy, and usually kills unwanted RF propagation channels (such as power supply lines to/from oscillator, buffer, amplifier, ...).

Unfortunately I have never been able to find any datasheet for those beads.

Roger, please post your results if you try your "donuts" for RF applications.

Roy , Tnx for your interesting comments.
What surprises me is that ,as you highlighted , ergonomics no longer seem to be important in scope development.
Whereas in other industrial activities and product design ,industrial designers pay a lot of attention to ergonomics.
Perhaps it is that modern scopes (and similar equipment) are designed by nerds for nerds.
It also adds to the perception that one has to be a 'specialist' to operate and use this type of equipment ,which I fear is an ever increasing element of modern marketing . A 'KISS' approach apparently does bring in the $$$.

==========
A practical way to determine suitability at HF and higher is to fit the
toroid with a bifilar winding ,being the primary and secondary of a
transformer.

Connect a signal generator to one winding and a RF millivolt meter or scope
to the other. By changing the frequency you quickly know in which
frequency range the toroid will be useful.

Usually 'blue' coloured toroids are ferrites for the lower frequencies
serving in SMPSes and AC supply filters.

say?
==========
If your supply voltage is 12 V and need 5 V @ 450 mA , you have to get rid
of 7 V @ 450 mA or 3.15 Watts
in whatever way you do that . Suggest you stick with the 7805 , and
increase the regulator's heat sink if that makes you feel happier .
You can also spread the heat by adding a resistor 'upstream' of the voltage
regulator.
Say you drop 4.5 V across the resistor which @ 450 mA would have to be 10
Ohms ,2 W (take a 3 or 4 W resistor)
Locate the resistor off any PCB (preferably using ceramic ferrules) in a
relatively open area ,not too close to other components
The voltage regulator would then only have to dissipate 1.15 Watt .

With a switch mode regulator you might introduce RF problems.

An inductor in series with the varactors, then another one in parallel
with the series combo can get you a very wide range of impedance from a
decent varactor.

Cheers,

Phil Hobbs

>For CW you need a tunable VFO and this is not easy with reasonable stability
>You wiull have to use an HF transceiver as a tunable IF

If you are _only_ interested in the 2m CW band around 144.050 MHz, a
VXO should give a sufficient tuning range.

A fundamental mode crystal (i.e. below 20 MHz) can be tuned by
500-1000 ppm with a series inductance and variable capacitor. This
should give a 70-150 kHz tuning range on the 2m band.

If a 10.7 MHz IF with low side injection is used, the required LO
frequency would be about 133 MHz is needed, which can be done with a
14.82 Mhz crystal and two triplers or with 16.67 MHz crystal and three
triplers. High side injection should also be checked, since these may
give crystal frequencies that are easier to obtain.

These days the doublers and triplers can be quite easily implemented
with MMICs (such as MAR-x series) and bandpass sections between the
stages.

MMIC:s have reasonable noise figures for the 2m band even as RF front
end amplifiers, but sufficient front end selectivity is often required
to avoid overload problems if the gain is very high.

Right. I might make the series inductors symmetrical, if I needed the
tap point to be near signal ground (e.g. with a centertapped coil or a
differential pair driving it). Last time I used this trick was in a
160-MHz phase shifter. The two inductors will generally be about the
same size for best results with a hyperabrupt varactor--5 minutes with a

math program will give you the right values. Generally you need to keep the reactance capacitive if you're resonating a crystal against this combination--there are multiple operating frequencies otherwise, since the resonator will look capacitive almost everywhere.

Cheers,

Phil Hobbs

(snip)

Fair-rite makes many of these beads, and their catalog has some
impedance versus frequency data for them:

http://www.fair-rite.com/products.htm

You can also roughly sort ferrite material roughly versus frequency
capability by measuring the resistance with an ohm meter. Low
frequency power types measure in the hundred or thousands of ohms
between contact points, RF suppression types measure in the high kilo
ohms, while high Q RF types measure in the meg ohms. Having a few
known samples for calibration purposes helps.

At VHF/UHF most inductance formulas lose accuracy because the thickness of
the wire,
used to make the inductor, can no longer be ignored.

So the right way to do this is to lower the _effective_ minimum
capacitance. You can do that by adding an inductor, to cancel out
capacitance. You can end up making the tuning range as wide as you
want, but at the expense of the crystal (ceramic resonator in your
case) being less of the overall frequency determination. In other
words, there comes a point where you'd be as well off to just do an LC
oscillator. But to double, say, the range, it's a good way to go.

I guess I re-discovered what was already well known, but a few years
ago I designed such a VCXO, and was amazed how linear the
freq-vs-controlvoltage curve was (a good thing for use in a PLL).
Don't know what range you're trying to achieve, but I had no trouble
getting a bit more than 0.1% (~20kHz at 14MHz) that way, with a
crystal.

Cheers,
Tom

Oh bugger. Well how about using varactors with a higher C/V ratio?

>If you're not already using a "hyper-abrupt" type of varactor, you should
>look into one. They offer a wider capacitance range.

Not sure what you mean by that term, but imagine it amounts to simply
a type with a higher capacitive reaction to applied voltage - as I
mentioned above.

>What type of varactor are you using, and what's the frequency of the
>resonator? What's the application...linear frequency modulation like FM or
>data keying like FSK???

I'm currently using BB149A diodes, but I've got some BBY40s as well,
which might offer more shift per volt; I haven't checked the spec yet.
The fundamental frequency is 8.00Mhz and I need to pull it by +/-32khz
for tuning rather than modulating purposes.

I'm using a 555 timer to generate a sawtooth waveform to feed the
diodes, so I get a constant frequency sweep at the vcxo's output. Main
problem is the limited voltage output range; starts above zero volts
and peaks well before supply rail. So not much of a ramp; just around
4 or 5 volts, I guess. I could try changing the diodes for more
responsive ones but they're SMDs and I really hate messin' with 'em.

Well, I have no "un-named" sources, only the named ones. For two
interviews with Howard Vollum, co-founder of Tektronix, try:

http://www.infoage.org/oh-howard-vollum.html

Infoage is concentrating on the Signal Corps labs, most notably
Camp Evans, NJ (outside of Fort Monmouth) which became the
"Evans Laboratories," an adjunct of Fort Monmouth (along with
Coles and Squires labs outside of the Fort in the 1950s). Vollum
spent some service time at Camp Evans after overseas work on
radar in Great Britain. Vollum's interviews consist of one in 1955
and another in 1980.

There's some more at:

http://www.ohsu.edu/vollum/about.htm

There's also archive material from EE Times and several Tektronix
collector's web pages.

I don't find any reference to Hewlett-Packard, but more on the rivalry
with Allen B. DuMont and his oscilloscope company.

My own acquaintence is first with the 511AD model in 1954 while in
U.S. Army and becoming a supervisor on microwave radio relay
equipment. As far as I can recall, the sweep trigger of the 511 is
little more than a Schmitt Trigger circuit which was rather common
in pulse circuitry of the 50s. All of the first Tektronix scopes had
regulated power supplies which enabled the stability of the vertical
sweep to give true volts-per-graticule-marking information and for the
sweep rate to be calibrated with some precision. Whether in service
and maintenance or engineering design, the true information on the

trace is more important than whether or not the sweep trigger is fancy (which it was, again, stable to use repeatedly thanks to the regulated HV supplies). Add to that the "unblanking" of the CRT while in sweep (blank screen during retrace) and the display is quite natural and easy to use.

Having used a number of different instruments and scopes, I can't agree with the "standard control arrangement" comments. Each and every instrument has, to me, ALWAYS had some differences which required attention to the bell and whistle control lay-outs. This got worse by the 1970s when more and more function controls were added to the front panels and the sizes of controls got smaller and smaller. My fingers remained the same size...it got ridiculous with the pointy little "keys" of the optional 7000 series (?) plug-in for writing things on the CRT face...and the plug-in "spectrum analyzer" modules from a company that Tektronix acquired.

Given the rather totally different function controls of today's DSOs, it boils down to everyone needing to understand their instruments FIRST before trying to use them. Ain't no such thing as "standard control arrangements" when the controls don't apply to newer functions.

>4 or 5 volts, I guess. I could try changing the diodes for more

The 555 thresholds are set to charge and discharge the timing cap at
1/3 and 2/3rds the supply voltage. If you using that directly the
easiest way to get more "swing" is :

Use an opamp to translate the voltage lower and add some gain
(use at least 12v on the opamp). That can get you a Tuning voltage
that is near 0 to near 12V (that should help).

OR use a higher Vcc on the 555, say 12v. That will get your total
swing to about 4V and the low will be 4v and the peak will be 8v.

There are tricks that can be used to "offset" that 1/3 and 2/3 point
but the total swing is usually the same. That can help as operating
the Varicap closer to 0V will allow you to use more of it's
capacitance range though it's usualy less linear at the bottom.

Myself I'd use an opamp to create a saw generator and then I can
control the swings.

Allison

Yes, if you use dash for "1", dot for "0" (or vice versa), _never_
mis-send, and have some unambiguous way to signal EOF, or use
some other coding scheme that unambiguously represents all the
possibilities as stuff that can come out of a spark transmitter. The
EE and mathematicians who know more coding theory than I do will be
better able to answer the question, but _yes_ is the basic answer.

If you want to send it synchronously, then it's even fairly easy,
provided you're prepared to accept a low data rate and do signaling
out-of-band for EOF, End-of-track, and suchlike.

After all, we manage to send images from probes passing Neptune. This
is, by comparison, trivial.

(I'll skip the lecture on Gold codes, sending a 65535-bit PN sequence
straight-up for a "1", inverted for a "0", and all the other stuff
that actually got the bits received with a minimal BER)

Let me know if you want to start sending low-rate digital audio using
your spark-gap transmitter, and I'll move a few thousand miles away.

Related note:

Did anyone else here in the US catch the piece on NPR about Bill
Marconi's first transmission from Poldhu to Newfoundland, about a
week ago? It was sort of spacey and low on information content, but
it _did_ have some stuff in it I hadn't heard before, including audio
of Marconi talking about the problems involved -- including the winds
at Poldhu being so bad that they repeatedly blew the antenna masts
over.

Last time I used this was with an MV104 common-cathode dual hyperabrupt, to make a 110-MHz phase shifter. It used a Mini-Circuits quadrature hybrid in the usual way, coming in the 0 degree port, coming out the 180 degree port, and hanging matched reactances on the 90 degree ports.

Each section had its own inductors, and the cathodes were bypassed heavily (1000 pF) to ground so that the two sides didn't interact too much. The component values were 45 nH in series and 43 nH in parallel. It was linear to within +-4 degrees, and the one section gave phase shifts from 12 to 164 degrees, both dramatically better than I could get with a bare varactor.

The idea is to have the varactor resonate with the series inductor just off the low-voltage end of the range, and have the series combination resonate with the parallel L just off the high-voltage end of the range. Since the series-resonance doesn't even notice the parallel L, the design equations decouple nicely, too. You adjust the placement of the resonances to get the range and linearity desired.

Cheers,

Phil Hobbs

I had to smile when I read this. I realize that there certainly are
jobs out there which require this kind of bandwidth, but I think for
the vast majority of us, 20MHz is more than enough.

I know that I often pull the 20 MHz bandwidth limit switch on my 465B,
just to quiet down the noise, and I actually have a 10 MHz scope which
is still extrememly useful.

It's nice to know that the extra bandwidth is there, but for almost
any servicing job (TV, radio, CD, DVD, audio...) 50 MHz is way more
than enough.

Looks like this amp was designed for 3 811A's (three sockets), maybe he dropped
one of the tubes?

BTW I built an amp almost as ugly about 15 years ago using a pair of 4-400A's.
Mine was at least safe, and it even worked on 80-20, above that the tank was not optimal and it worked poor. On 80 it tuned as broad as a barn, but I've seen SB-200's do that too. Mine was built in a pair of boxes one on top of the
other that came out of a surplus computer system. The top box was the rf box (used
to hold the disk drives) the bottom box was the power supply (used to hold the rest
of the computer) so it looked like a sick Henry 2K. The only power transformer
I could find had a 120v primary, but it was good for a real 2kw. (when ever I tuned up for more than 20 seconds I blew the 20A breaker). The plate supply
was plugged into one outlet on it's own line, the relay and filament supply was
plugged into a second outlet on a different line. I had a FWB rectifier using
1N4007's, each leg had 10 diodes in series with equalizing resistors and caps
(WAY over built). The secondary put out almost 3kv no load, so the tubes were

running a little over 4kv. The filter was 10 400uf 450v computer grade caps
in series, with 20k resistors across each. A real MONSTER of a supply.
There was a power resistor in series with the primary that was shorted
out by a relay
across a sensing resistor in series with the primary as well. This gave
the HV
supply a soft start so the capacitors charging wouldn't zap the diodes.
Wish I kept a photo of my Frankenstein machine.

> Told you it was a dousy of a question, whats your thoughts.

Conceptually, you're describing something similar to
ODFM, used in 802.11(a) and (g). Basically, you create
numerous independently modulated carriers across a band,
combine them and amplify them. If you're intent on
transmitting the same information on each carrier, then I
suppose a simplifying trick might be to produce a comb,
but the general case is basically identical to something
that exists already.

Now, here's a question that follows - suppose you built
an ODFM transmitter that was able to place a signal on
each 'channel' in the FM broadcast band. What could
power-level/signal-strength would be permitted under
Part 15? Would the aggregate ODFM signal be considered a
single signal for Part 15 purposes, or would each 'channel'
be considered an independent signal (since, technically, it
is)?

4214. Remote Cutoff Pentodes in Regens

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-11 18:24:17 UTC
From: kizerian@xmission.com
Message-ID: <ee6182da.0312111024.418b2687@posting.google.com>
Source record: 30331

I have seen remote cutoff pentodes such as the 1T4 used in regenerative receivers. I'm guessing there is a good reason...perhaps something to do with the decrease in gain with increasing signal level...so that the pentode oscillator "fights" going into to oscillation enough to give a very smooth transistion...rather than the more abrupt transistion of some solid state circuits.

I know of no solid state equivalent (without some sort of AGC feedback loop) for the remote cutoff pentode. Does anyone know if there is?

And speaking of the 1T4...has anyone played with these enough to give me some ideas for using them in regenerative radios. I also wondering how much you can starve the plate and still get good results in a regen receiver.

Thanks

>> Nonsense. General Radio had a nice little formula way back
>> before 1956 for finding the distributed capacity of an inductor.

If you are measuring an inductor that has distributed capacity, you
are actually measuring BOTH L and C together.

If the measuring instrument is calibrated in inductance (most Q
Meters are), then the "inductance" reading will be in error at
frequencies near self-resonance. That error is NOT in the
instrument. It is the cause of measuring TWO things at once.

To find the real value of the inductance, another measurement way
is required to derive the distributed capacitance. That way uses the
calibrated capacitance of the Q Meter and the ability of the Q Meter
to set measuring frequencies in a 1:2 ratio.

The calculation required is minimal and the result finds the true
inductance of the coil...as well as the equivalent parallel
capacitance of the windings' distributed capacity. Once those two
values are known, it is an easy task (again, minimal calculation)
to determine total reactance of the whole coil.

The inductance of the coil assembly will NOT change due to
frequency. Reactance of the coil assembly does change with
frequency and follows the basic relationship for the COMBINATION
of inductive reactance AND capacitve reactance in parallel.

In practical matters, for most of UHF and below, the distributed capacity of a "coil" is least with a toroidal form, is greatest with a solenoidal form having overlapping layers of windings. Single-layer solenoidal forms are in between. Spaced-out turns on a solenoidal form (one to two wire diameters' gap between turns) also approaches minimal distributed capacity of the coil. That's one of the reasons I did a bunch of tests with solid wire coils formed on common screw threads a few decades ago...to get some practical data and quit all the "intellectual arguments" on inductance formula values. :-)

Again, in practical matters, a 1.0 uHy coil is not likely to be used in any tuned circuit within an octave of 100 MHz...and the distributed capacity of that 1.0 uHy coil is likely to be less than 1.5 pFd. The amount of error in application as a tuned circuit at 10 MHz that uses an added parallel capacitance for resonance is likely to be less than the tolerances of individual component measurement error capability.

I suppose that all these "intellectual arguments" (the kind done without touching parts or instruments) is "fun" in a weird, wired way, but it is so much phlogiston tossed on the web. When push comes to shove on the bench, one has to do some internal thinking about what is being measured, what the measuring instrument is doing (at least in general) when it is presenting data to the user. To measure a "coil's" properties it doesn't matter whether it is a Q Meter or some kind of bridge...every user needs to know what the instrument is presenting and whether or not it presents data as a combination of components of the "coil."

A common "dipper" is usually one of the worst kinds of RF measuring instruments for qualitative data. The oscillation frequency of the dipper is pulled all over the place by external coupling (easily seen by a very loosely coupled frequency counter). A dipper is good only for quick, rough indications. An absorption wavemeter is better but very rare (frequency is much more stable). A Q Meter with a calibrated variable capacitor is best but also expensive as #$%^!!! The in-between instrument is a bridge of some sort but that bridge isn't guaranteed to sort out the difference of THREE components: Resistive part and the imaginary part due to combination of inductive and capacitive reactance. Bridges vary in types and ability to separate the components.

With the ability of newer specialty ICs to separate magnitude from phrase angle, there's a whole new set of instrumentation possible to do L-C combination measurment. That started with vector voltmeters three decades ago and several homebrewers have adapted Analog Devices and others' ICs for some decent bench instruments that can be made and calibrated in the home workshop. Those operate a bit differently than passive-element bridges but can yield qualitative data on "coils" and "condensers" as good as passive instruments. With the aid of good calculators (an HP 32S II costs $65) anyone can get down to fine nitty-gritty detail and include compensation for other

things. [see other thread on homemade vector voltmeter progress]

Or...one can get on newsgroups and argue the Whichness
of the What in jolly flamefests that last weeks. :-)

hi
i have read ad9830 dds ic datasheet, but i have steel problem how i should program it, for example i want to use pararel port for interfacing , and for example want 3.1MHZ on out put, how i should use D0 to D15 and A0,A1,A2? should i use both freq reg (0,1) and all 4 phase reg ? or one is enouth?
any help would be most appreciated
thanks
payam

Use a switching regulator -- you can even get an LM317 to "oscillate" by putting an RC network in the feedback network -- and use it as a buck converter -- the schematic is on the Nat Semi website -- just search under LM117.

>oscillation enough to give a very smooth transistion...rather than the
>more abrupt transistion of some solid state circuits.

A 1T4 is an old directly-heated cathode tube. Played with those
a 56 years ago...in regenerative receivers...:-)

Looking back at those old magazine article projects, I'd surmise
that the "reason" a particular tube was used was that it was
AVAILABLE to use.

A regen operates at the hairy transition of self-oscillation where
positive feedback yields a tremendous increase in gain. Doesn't
matter whether it is vacuum tube or transistor. The only difference
between remote-cutoff and sharp cutoff characteristics (transistors
of the bipolar junction type are very sharp cutoff equivalents to
tubes) would be on the amount of spurious garbage created when
the regen jumps into full oscillation.

>I know of no solid state equivalent (without some sort of AGC feedback
>loop) for the remote cutoff pentode. Does anyone know if there is?

"AGC in a regen?" If you bias the control grid of a 1T4 about all you
will do is change the feedback setting for that hairy transition just
prior to going into self-oscillation.

>And speaking of the 1T4...has anyone played with these enough to give
>me some ideas for using them in regenerative radios.

The last time I played with battery-filament tubes (including the 1T4)
was in helping a friend restore an AN/PRC-8 Korean War era walkie-
talkie in the 70s (I wore one once in 1953). Nice VHF FM transceiver
very stable. The first time I played with a 1T4 was in a regenerative
receiver back in 1947 and it was very touchy on feedback setting
versus frequency on MF to HF bands (plug-in coil thing).

>I also wondering
>how much you can starve the plate and still get good results in a
>regen receiver.

Experiment with it. There's not a large amount of data on regenerative receivers any more and very little in the way of vacuum tube info. A 1T4 power demand is minimal, 1.5 VDC filament at 50 mA and about 2.4 mA plate and screen current at 45 VDC supply. [183 mW total supply drain] That's fairly "starved" considering the transconductance is only 700 umhos (typ) at 0 VDC control grid. Even at "maximums" of 90 V plate and 67 V on screen, the transconductance is only 900 umho.

A 1L4 is a close cousin to the 1T4 as a sharp-cutoff pentode, same envelope, filament, etc., but the gm is about ten percent higher. A 3Q4 or 3S4 (a 1S4 was made but was not recommended for new designs back in 1956) has a gm of 1500 umho at twice the filament voltage and 8.8 mA plate+screen at 90/67 V. Those "power pentodes" have a semi-remote-cutoff characteristic. [800 mW power supply demand would be "power" from a battery pack way back then...]

Regenerative receivers were all the rage among hobbyists back about 1930 when tubes were relatively expensive and lacked transconductance for effective RF amplification. Such were a cheap way to get more sensitivity out of a single tube stage...but at the expensive of instability and lack of uniform selectivity. Once the superheterodyne was into production, it proved far better overall.

For experimentation purposes, a high gain-bandwidth product op-amp IC might produce some interesting results. The gain-bandwidth (or 0 db open-loop gain frequency) of some op-amp ICs is up at 30 to 70 MHz now and the DC open-loop gain is enormous in comparison to vacuum tubes. I sense possibilities of an op-am regen or even a superregen on up through HF. Just a thought... :-)

4220. Battery replacement..

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-11 23:10:56 UTC
From: Joel <Joel@cyberbest.com>
Message-ID: <qQ6Cb.3622$1k5.821744755@twister1.starband.net>
Source record: 30337

My NiCad battery gave up the ghost in my HT for the second time. They only seem to last a few years, at the most. I was wondering if I replace the NiCad's with newer NMHi batteries can I use the same charger? Both type batteries are about 1.2 volts when charged. But I'm not sure about their charging requirements.

Joel AG4QC

>My NiCad battery gave up the ghost in my HT for the second time. They only
>seem to last a few years, at the most.

Not uncommon. NiCd batteries _can_ have a fairly long service life
(up to 1000 charge/discharge cycles) if treated gently.

Unfortunately, in many applications they aren't treated gently...
they're run down all the way to zero (which tends to reverse-polarize
the weakest cells and damage them), and are recharged too rapidly
without proper charge management.

Even when treated very well, 1000 charge/discharge cycles wouldn't
last you more than 3 years if you run 'em down fairly far every
day, and recharge every night.

> I was wondering if I replace the
>NiCad's with newer NMHi batteries can I use the same charger? Both type
>batteries are about 1.2 volts when charged. But I'm not sure about their
>charging requirements.

In general, I believe that the answer is "maybe".

NiMH batteries can usually be trickle-charged using the same basic
method used for NiCd batteries. If your HT and its charger normally
required somewhere between 10 and 16 hours to fully recharge your
existing battery pack, then it'd probably work well enough for NiMH
batteries.

Fast-charging is a different issue, because the methods used to detect
"full charge, stop cramming!" on NiCd and NiMH batteries are somewhat
different. A fast-charge circuit originally designed for NiCd
batteries only, may end up damaging NiMH batteries.

Many of the aftermarket-batterypack companies which advertising in QST
etc. will either sell you a NiCd-based replacement pack, or a
NiNH-based pack with the option of buying a NiMH-aware fast charger.

I seem to recall that NiMH batteries can use the same chargers as
NiCd. HOWEVER -- LiON batteries cannot.

I'm sure others will correct me if I screwed up. ;-)

Some of those battery packs have more than 2 contacts, I think the
reason might
be extra internal compoenents that help detect when the charger should
shut down.
A NMHi battery pack made to replace a NiCd for a specific radio might
have the
correct network in it to work with the original charger.

In addition to the other postings here, do a Google groups
search on "nmhi" , or "battery" over in

rec.photo.digital

Those folks talk incessantly about using NMHi batteries. And,
due to their intense need for good battery service life, there
are some pretty knowledgeable folks there with suggestions.
As well, there'll be some refereneces to web sites with
beau coup technical talk on using NMHi batteries.

I am reading through the 2003 ARRL Handbook, learning about circuit design, characteristic curves for common emmitter configuration, load lines and such things, just about ready to test all this exciting knowledge on a simple amplifier stage using a 2N2222 transistor and now I can't find the set of characteristic curves for this transistor (I actually downloaded the spec sheet and looked).

Where is this set of curves to be found? Is it not part of a regular spec sheet for a transistor??

Baffled

Uwe

Gee, Ian, you only will have to go out and do
the short-open-50R calibration at the end of
the coax. The software can move the reference
plane from the VNA out to the antenna feedpoint,
and you can do the rest from the comfort of
your shack!

Yes, I'm on Harold's list for a kit.

73, John - K6QQ, who thought that after retirement
he'd never have the use of a VNA again!

Here is a curve for the 2n2222.

http://hibp.ecse.rpi.edu/~connor/education/IEE/lectures/Lecture_3_Transistors.pdf

http://hyperphysics.phy-astr.gsu.edu/hbase/electronic/loadline.html

Go about 3/4 the way down the page.

The curves are in many books the manufactors publish.

> the regen jumps into full oscillation.

But it does matter. In the heirarchy of regen devices tubes provide the "smoothest" regeneration, followed by FETs, with bipolar transistors generally taking a distant third. I am not asking because I have never built a regen. I have built DOZENS of them, and I sell a simple version on my website...but I'm always looking for a new approach.

> >I know of no solid state equivalent (without some sort of AGC feedback

> superregen on up through HF. Just a thought... :-)

The voltage gain of an effective regenerative stage is can be as high as 100,000 as reported by Charles Kitchin. That's 100dB...not many op amps have that kind of gain at say 10MHz.

Thanks for your comments. I always appreciate hearing from folks with lots of valuable radio experience to share.

The old single conductor shielded "Microphone cable" with a braided
shield was commonly used with these connectors. Belden, Alpha,
Consolidated wire and other companies made the cable, and you should be
able to ge a little at a music store that does repair, form a commercial
sound business, or any electronics parts house that sells cut cable.

It used to be sold on spools as small as 25 feet, but I haven't
bought any in years. I may have some scraps, but I would have to look
for it.

Hi all,

I wanted to build an RF relative field strength meter, so set about searching on the Web for any existing designs. Those I turned up weren't particularly impressive, so I decided to start from scratch and design my own. I've just completed that this afternoon. I've allowed for 0.25mV input to give rise to FSD on the microammeter. Question being, however, is that going to be sensitive enough? Does anyone have any idea what the field strength in microvolts or millivolts is from a half Watt transmitter at about 6 feet away? I guess I should have posed this question *before* designing it, but who among us can honestly say they haven't designed something without knowing what the spec is? :-)
Anyway, ballpark figures gentlemen, please.

Hi all...
I am currently using a homebrew 35 amp power supply that has a 50 amp blocking diode in series with the B+ line going to a lead acid deep cycle battery to feed two hf rigs and one vhf/uhf rig.

The power supply has no real current limiting and I want to insert a bit of resistance in the B+ line to keep the current from exceeding 8 amps or so on battery charge up. Can anyone give me an idea of what value would be appropriate.

I am also thinking of replacing the deep cycle battery with a sealed battery...one of those that is advertised to never need fluids, won't leak, etc....are these appropriate for this application?

Thanks in advance....de Denton WB7TDG

>sheet for a transistor??
>
>Baffled

The two links provided by Ralph Mowrey are good ones and the first
has an "approximate" set of curves for the good old 2N2222.

Contrary to what Ralph said, manufacturers seldom publish
collector-v-base curves now because few designers use such
information. Silicon BJTs are so nice and straight-line-ish on
the common-emitter collector graphs that it isn't needed. The
only non-linear part is at very low collector-emitter voltages but
that is almost a given and the same for every transistor.

Vacuum tube internal geometry variations created the variations in
"plate curves" along with the different types of pentodes: Sharp
cutoff, remote cutoff, etc. Positioning of the electrodes in the
electron stream and their interaction with each other created the
different curves. With transistor junctions the only variation is the
low V_sub_CE and low base current...which can generally be
graphed by hand from a variable bench supply without blowing up the
device. In trying to create one's own curves at high V_sub_CE, a
pulsed supply MUST be used or the transistor dissipation ratings are
exceeded.

If you are going to present a low-resistance DC load to a transistor
driver but the load is a medium-impedance at RF, the collector
current is chosen from two main factors: (1) Small-signal h_sub_fe
(which can vary from lot to lot and sometimes has its own curves);
(2) Collector-emitter junction dissipation (it's the full V_sub_CC times
the collector current at DC). That holds at AF as well as RF if the
circuit is a transformer-coupled amplifier.

If you are doing something like a "resistance-coupled" amplifier, then
you can trust the curves to be nice and straight and set the "load

line" center point by arithmetic. Voltage across the load resistor is the same at DC as at AF or RF...but the LOAD impedance of the driven stage is going to be in parallel with that resistor...plus the h_sub_oe (internal resistance of the collector-emitter junction) at AF or RF.

FETs are the closest active device to vacuum tubes. Very high input impedance, drain voltage signal variation a function of trans-conductance times total load impedance. A no-sweat calculation. Bipolars are another story and gain of bipolar stages MUST be calculated in terms of power out v. power in due to the base current being the input. Bipolar Junction Transistors (BJTs) have to be thought of as different from vacuum tubes' design rules.

As you go into frequencies approaching the "transition frequency" or f_sub_t, there's a whole potfull of new and different curves for BJTs that tubes never had. Those ARE published on BJTs designed for RF work; to use them properly, you must also know complex number quantities and admittance-impedance transformations (not hard at all with a good scientific calculator).

For applications at frequencies below about 1/20th of the f_sub_t, no problem on not using collector-v-base-current curves. You will find that there might be some small-signal current gain variation at different collector currents and some BJTs might have curves for that. Load lines with BJTs in linear amplifier circuits gets a bit unneccessary.

If you are speaking in general terms then there are plenty of gain-
control elements out there. For a single-IC type of device, the
old Motorola MC1350 (8-pin DIP) is a sort-of Gilbert Cell arrangement
inside, differential-in, differntial-out, constant parallel Z-in of 5 KOhm
in parallel with a couple pFd each input. The gain control portion is
done by "starving" or actually redirecting the DC emitter current in the
input differential pair. Jameco (www.jameco.com) still sells this IC
at around $1.20 (?) in singles and has a copy of the Motorola data
for download on their website. That datasheet has a schematic of the
insides. That's good up into mid-VHF.

Some of the older JFETs had non-linear source-drain curves v. gate
voltage curves...see the difference in biasing for "depletion" and
"enhancement" mode operation. I don't know if they will work to
the top of HF range, though.

I was suggesting using op-amp ICs WITH positive feedback. :-)

I'm just not going to buy "100 db voltage gain" in a regen based on
my own experiences...unless I see the bench layout and check the
calibration stickers on the test equipment determining this. :-)

Frankly, to get a simple receiver for HF, the Tayloe Mixer and its
separate LO followed by a low-noise AF range op-amp has the
most sensitivity for the fewest parts...and with little possibility of
re-radiating the oscillations of a regenerative due to a twitch of the
regeneration control. As a direct-conversion receiver, it can handle
CW or SSB and, with a stable LO, can take in conventional AM
with a lot less tweaking than a regen with a touchy regen control.

The most stable regen I ever built (three in all, the first using that
1T4) was with a 117N7 beam-power pentode and rectifier diode, AF
out driving an old, old high-impedance dynamic speaker. Plate curves
of that tube were of the sharp-cutoff variety. AM BC band, not much
else to listen to for entertainment in 1948. I suspect it was acting
more like a "plate detector" but it had the sensitivity of a common
"all-American-five" AM table top radio receiver.

Some of the minimal-tube-complement receiver designs of older times
used regenerative detectors at the IF for sensitivity improvement. I
know of one old Hallicrafters S-38 (?) reworked that way. That receiver
had essentially an "all-American-five" tube lineup and no power
transformer. Somewhat unsafe, but useable.

Nostalgia isn't what it used to be...

>appropriate.

If you want to limit the charging current to a maximum, then you
need a current-limiting regulator circuit with some form of current
sensing in series with the battery line.

A series "resistor" can be made from standard magnet wire with the
value of resistance taken proportional to the resistance per whatever
length is stated. Copper draw dies and general manufacturing of
magnet wire, plus slight changes in dimension due to winding it all
up on some kind of form, allow about a 10% tolerance on such a
"resistor." A very small value resistance is hard to measure in the
home workshop environment so a length of magnet wire is a
reasonable substitute.

Any common op-amp can be used to sense the voltage drop across
a milliOhm resistance (the magnet wire "resistor"). The voltage drop
will be in the milliVolt range but the op-amp can amplify that to drive
a meter or whatever. If put in the return lead rather than the hot lead,
you avoid most of the "swing" in voltage possible in the hot lead. With
only milliVolt drops in the sensing resistor, there isn't a great deal of
upset with to the charging voltage. That sort of current measurement
can be used both for visual indication of charge current and for coupling
to the current regulating circuit.

["B+" is the very old term for plate voltage supply for tubes, ain't really
appropriate for these new-fangled contraptions known as
semiconductors...:-)]

If the charging circuit is basically a constant-current supply (which can
be set), then the output voltage will be set by the battery being charged.
The charging can be halted by limiting the maximum voltage supplied
to the battery(s). That's the opposite of what is normally done; i.e., a
constant-voltage supply with a high current limit. Just as feasible in
practice to have either constant-voltage or constant-current. Some of

the older power supply manufacturer's data will explain various regulators' configurations. I used an old Kepco softcover book back in the late 1960s as a model for a "universal" bench supply.

It isn't clear how you have the arrangement of charger, rigs, and blocking diode(s). There's all sorts of variations possible on those. Any blocking diode will always have some voltage drop across it in forward conduction. For a silicon diode that is in the neighborhood of 0.6 VDC; at 8 A that is 4.8 W of loss across the diode. That will also affect the charge voltage. If you "float" the charger across the battery, then you have to account for that and keep the radio primary input current from affecting the charger.

You aren't accomplishing much but just sticking a resistor in series with a charger supply. If the series resistance is high you create a quasi-constant-current supply with a wide variation of output voltage (called "compliance" in constant-current circuits). If the series resistance is too low, there's little compliance and voltage is basically that of the basic charger rectifier and capacitor.

>I am also thinking of replacing the deep cycle battery with a sealed
>battery...one of those that is advertised to never need fluids, won't leak,
>etc....are these appropriate for this application?

Those should work fine - provided - you stay within battery manufacturer's ratings.

Uninterruptible power supplies exist in the tens of thousands out there in cyberland with little problem. Their internal batteries are sealed and the chargers float across the battery regardless of the load being on or off.

Use ohm's law. The voltage drop across the resistor will be the supply voltage (13.8) minus the discharged battery voltage (10 volts) or 3.8 volts. R = E / I so 3.8 / 8 = 0.475 ohms. So a 0.5 ohm resistor. The power disipated is I*I*R or 8*8*0.5 = 32W.

The battery voltage will quickly climb and the charging current will drop accordingly so the battery takes longer to charge this way but it should be fine if you normally "float" it across the supply to keep it charged *and* it will protect the battery and the supply from over current when it is discharged.

Figuring the field strenth of a .5 W xmtr at 6 feet is difficult. Depends on the antennas on the xmtr and the FSM and their polarization. Also, depends on the sensisitivty of your FSM (field strength doesn't depend on sensisitivty but your reading will).
Since this is a *relative FSM* I would get something working, use that as a reference, and go from there.

Thats the way its done to pull crystals a long way.
The thought/real experiment to assist is to assume that the acoustic
resonator is resistive (zero phase) at series resonance.
The maintaining circuit can then be replaced by an equivalent resistor.
The circuit with resistor should oscillate at approx the resonator
frequency.The inductor across the varicap is selected to almost tune
out/parallel resonate with the varicap.
The series inductor is phase retard to ensure the maintaining circuit
tis zero phase . Adjustment of the varicap then moves the circuit above
and below the series resonance of the resonator.

I'll SWAG & hope I'll be corrected if I tell ya wrong. Assuming a 1/2 wave antenna on the xmit & rcv, take the volts/meter you're applying on the antenna, divide by 4 PI / (distance)^2, with distance being in wavelengths.

Then there is the famous propogation equations which involves 32, recieve and transmit antenna gains, and the log of the distance and frequency. You can then go from power to voltage according to the antenna Z. I'll look up the equation for you if you don't get a better answer.

>
> p.
>

E = sqrt(30PG)/d Volts/meter - Field Strength

P = Tx power
G = Tx antenna gain - and don't forget the gain of the meter's
dipole.

S = PG / (4.pi.R^2) Watts/meter^2 - Power density

R = distance

S = E^2/377 (E field^2)/(Z of free space in the far field)

Where the far-field starts is antenna dependant, but it is
acceptaed the the boundary is where the inverse-square-law for
power density above becomes invalid, that is, as you approach the
antenna, the rate of change of S decreases and S is no longer
inverse-square-law dependant.

For large aperature antennas (dishes, dipoles, etc.) this seems to
work out to

R = 2L^2/lambda

lambda is wavelength and L is length of antenna

HTH,
Mike

How safe is it to run these without forced air cooling?

I've got one as a 1 - 4w driver (feeding a BLW60C) and although has a finned TO5 heatsink, it gets up to 70+ degrees Celsius when running. The Mitsubishi spec says it is safe up to 175 degrees Celsius but am not sure if what I'm doing will do the device damage?

Any thoughts anyone?

Neil

Yes; it belongs to Paul Kiciak.

And yes -

The original website URL is:

ï¿½ï¿½ http://users.adelphia.net/~n2pk/

ï¿½ï¿½ There is also a mirrored website at:

ï¿½ï¿½ http://www.qsl.net/n2pk/

Very briefly, it's a 0.05-60MHz VNA based on a DDS signal source feeding the Device Under Test. Output from the DUT goes to a 'zero IF' detector (multiplicative mixer) that converts to a DC signal level, which in turn goes to an ADC.

The local oscillator for the detector is a second identical DDS, programmed to the same frequency. Phase information is obtained by making two sequential measurements, one with the LO at the same phase as the signal source, and the second with the LO switched to 90deg.

Control is via the PC parallel port, which also accepts the signal level data from the ADC. The support software includes full calibration facilities (open/through for transmission measurements, and open/short/load for reflection measurements with a bridge attachment).

For such a simple concept, the accuracy is astonishingly high, approaching that of a commercial VNA. Paul Kiciak has investigated these issues very thoroughly indeed, and the results are fully documented.

Everything is on the website, including full constructional information, board layouts, software and extremely detailed documentation.

What you are descrbing is a "signal sniffer", not a signal strength meter.

Hello Paul,
have a look here,
http://www.alphalink.com.au/~parkerp/noapr97.htm

Here is a crystal set circuit.
http://circuitos.tripod.cl/schem/r85.gif
Convert it to a field strength meter by
Replacing the headphones with a large sensitive meter,
something big enough that you can still see the pointer,
when viewed from across the room. Bigger the better.
Use a germanium diode.
Use a metal box.
Use a short telescopic aerial.
Coil and variable capacitor to cover, 40Mhz,. 35Mhz and 27Mhz,
I am guessing those are the frequencies of interest, use
a switch if necessary to add/remove some turns or
add/remove a capacitor.

I know you have a grid dip oscillator so fiddling the
coil and capacitor values to get the frequency ranges

will be a snack for you.

Using your field strength meter only six feet away is too close. Keep it as far away as possible from your radio control transmitter but still being able to see it, that is the reason for the big meter movement. I am thinking of big cheap plastic 6 inch square types. Anything will do so long as you can see it from across the room and the movement is microamps full scale and not milliamps.

I am sure I have explained this to you yonks ago, well, if I have, never mind. maybe you forgot :-)

Set up your known good commercial radio control set at one end of the room, and field strength meter at the other side of the room. Note the meter reading. Now compare readings with your experimental transmitter. Is it more or less? Make adjustments to your experimental transmitter. This is the fun part.

I found that sitting my field strength meter (even though it had rubber feet) on my wife's metal serving tray reduced hand capacitance and made it nicer to adjust. So experiment with and without a sheet metal base. Maybe the first circuit without a parallel tuned circuit would be less fuss to use. Maybe you can knock up both types and tell us which was better. Heh heh heh....

I worked for Federal government for about 30 years,last 10 years I did
acceptance testing and evaluation of government purchases, mostly
Tektronix scopes,out of hundreds of new scopes I NEVER FOUND ONE
factory defect..Only two or three that had minor shipping damage from
improper handling,like fork lift dents etc.. in these cases Tek
replaced them instantly ,no questions. I have been to tek plants many
times for seminars, technical training etc..One of the most respected
companies ever to operate in this country...Tektronixs is not just

scopes,they have done a complete line of test equipment,medical ,TV broadcast equipment and many other lines. PLEASE,PLEASE lets get off this subject..Harold W4PQW

Who are you replying to? Paul did not say Signal Stength Meter, but
the guy you replied to kinda hints at it when he mentions power
level.

I would have to say that my 1GHz Signal Level Meter, which cost
$1500 would be the better than a relative field strength meter, but
if he measures say, 1V with his Tx off and 2V with it on, then
that's 1V and if his Rx antenna is a 1m dipole, that's 1V/m.

Neil:

Attached is a link to the Mitsubishi datasheet for the 2SC1947.
Regarding the thermal
specifications, the maximum junction temperature is 175C. The thermal
impedance is
15C-per-watt junction-to-case, and 150C-per-watt junction-to-ambient.

What this means is that the junction temperature will be hotter than the
case temperature
by 15C times the numer of watts dissipated. For example, if the transistor
is dissipating 4 watts,
the junction will be 60C hotter than the case temperature. Thus the maximum
case temperature
should be limited to 175-60 = 115C (pretty darn hot).

There will be some thermal impedance between the heatsink and the case,
but if well designed,
and well attached, it should be only 1 or 2 C/watt, almost negligible in
this example.

The 150C/watt junction-to-ambient spec means that the metal case of the
transistor is not
too effective at rediating heat by itself. Without any heatsink, and
assuming 1 watt dissipation, the
ambient temp would have to be limited to 175-150 = 25C (room temperature).

IIRC the original nation sw-3 used a remote cutoff tetrode as the
regen detector, with a remote cutoff tetrode as the rf stage.
Of course they were first referred to as "supercontrol" tubes.

There is loads of info on the net about regenerative recievers and
there are quite a few tube manuals online and lots of tube
information.

Most of the homebrews I have seen using the 1T4 use it hooked up in a
triode confiquration.........

Search the net.......Tube mansual online, tube data online,
regenerative recievers, homebrew tube radios,.......all the info you
want and more is on the net.

....and it is better when you can laugh about it.... sometimes it is
difficult to understand why your xtal won't operate on a 3rd or 5th
harmonic when it seems to work for everybody else - and you specified
proper overtone xtal for the manufacturer,
But it is a lot of bad constructions!

In the butler-type xo (popular in UK) you may operate a 27MHz xtal on
45 and even 81MHz (believe it was DCoDA who first described it)

But I believe the original question was something else? Xtals testers
were so popular in the 60's when amateur run around to surplus stores
buying FT-243 xtals, and several such xtal testers are described in
CQ, Ham Radio, QST, 73 DL-QTC, QRV, CQ-DL, Electron and other, they
run on fundamental frequency using colpitts or pierce type oscillator
and measured grid current as measure for excitation

Well,
soon I discovered the "fingertrouble" and deleted the first poster,
but the second question hasn't been answered until I made my own
measurements. Later posted a modified question, but no comments were
seen, so one may wonder if nobody else is experiemting any more?
The actual construction and variations are shown on
http://home.online.no/~la8ak/c13.htm
It is some frequency limitation, but not important since I need only
to cover the 100kHz to 10MHz band, so LPF and HPF should be added if
they can be made simple.
Suppose it is much gain in the first amplifier and this is the reason
for the bandlimit. We tested LA4WN's IC706 using a program, but it
seems to be some distortion in the audio stage so a simple external
product detector with some offset from zero beat is needed for more
real measurements where harmonic distortion on audio doesn't increase
the background noise level which is on the loadspeaker audio output

Unfortunately I forgot the box at LA4WN last night, and since he lives
220km away, the easiest would be to build a new version, possibly with
a more proper box, hi.

hi
my old bsr xl-1200 cartridge is wired onto the pins so it wont pop out with the 4 prongs as normal one's do. i think i could remove the wires and put each one onto the prongs of a new cartridge but it seems that the bsr cartridge is proprietary. there is one screw on top of the tone arm that holds my cartridge. i'm not sure it will screw into a new one such as the at3482u. anyone here ahve a solution? i could get another direct replacement for the bsr cartridge perhaps but i thought the 3482u (or another) would give me better sound than what i have now. i could perhaps just snap the new cartridge in without screws. all the wires in the tonearm are very thin so its hard to solder in there.
please email me a copy of your response.
thanks

Hi John,

Always nice to have your input. I did actually come across the circuit
you point to above during my search of the Web, but rejected it as
probably not being sensitive enough. I thought I could maybe do a
little better by having a stab at it myself - with the assistance of
LTSpice of course!
Many thanks to the other respondents to this thread, but no one seems
to have been able to SWAG the actual likely signal level in mV or uV.
So I thought what the hell and built my original design from
yesterday. I've just finished it and am surprised and pleased to
report that it worked fine first time! The sensitivity is a little on
the low side, but *remarkably* close to what I'd set out to achieve.
With a 100mW transmitter some 4 feet away, I can tune for 40Mhz and
tweak the sensitivity and get a peak at S9 on the CB radio type signal
meter I'm using for this purpose. That would have done me just fine
had you not suggested making the measurements from some greater
distance! So I either live with it as it is and use is at say 6 feet
away or stick in an extra voltage amplification stage for 'far field'
testing (do I *really* need this for my purposes?)
Incidentally, you were dead right about the tea-tray idea. It turns
out the grounded areas of the PCB really need to be earthed to a
decent, proper ground/earth rod via the mains supply. It makes a
huge difference to the sensitivity and drastically reduces the
annoying effects of hand capacitance when tuning and tweaking.
I'll post the schematic I arrived at later under another thread and
maybe someone can suggest a few mods that might up the sens. without a
complete redesign. Is it really that important to make the
measurements from 10 feet or more away?

If he puts two diodes in parallel he will double the capacitance and
will have to reduce the amount of inductance to have the same

min. frequency. Im not sure that the high end won't be greater than before, even though the capacitance ratio is the same, since the fixed inductance is lower.

Another idea would be to put the two varicaps in parallel, but switch one of them out as you approach the upper frequency.

Kenneth,

F=1/((2*PI)*SQR(L*C))

If you double C, you have to halve L to maintain the same frequency. If you do this, you only changed the LC ratio, not the delta tuning range.
The only way to get more delta F is to get more delta C. If you use the switching technique, you'll have a discontinuous tuning curve (Vtune vs Freq) which makes it hard to implement a closed loop tuning system. It can be done, but the control loop gets complicated.

A previous poster suggested what I'd called a "synthetic reactance", which is a series-parallel LC combination. This technique can produce very large effective-capacitance changes with a modest varactor range, however it also comes with the susceptibility of mode-jumping in the output frequency.

Because you didn't provide enough info, dude. That much could've
been inferred from the eqs I gave you. And you asked for "field
strength" in the wrong units. it's V/m or mV/m or uV/m. Hell I'd
give it to you in kV/m if you wanted. You'll never know what it is
if you can't determine the voltage present at the meter antenna's
terminals and it should be a dipole.

> So I thought what the hell and built my original design from

:) ! Adjust the meter to get the answer you want. Ok.

> That would have done me just fine
> had you not suggested making the measurements from some greater
> distance! So I either live with it as it is and use is at say 6 feet
> away or stick in an extra voltage amplification stage for 'far field'
> testing (do I *really* need this for my purposes?)

lessee 40MHz is 7.5m lambda so the far field starts at around 3.75
meter per the eq I gave you for that.

I think that 1st eq I gave was for a vertical and it's fucking with
me.

I'll use a distance of 6m.

since you seem to want to know power try the path loss eq

32.45 + 20log(f) + 20log(d) = 20db

f in MHz, d in km

10log(Pr/Pt) = -20dB

but EIRP = Pt.G

G is antenna gain and you didn't give that info.

so I'll use G = 1

Pr = 1mW

Pr.G = E^2/Z voltage at input to Rx

G is Rx antenna gain, I'll use 1

E = 224 mV rms

Let me know if I f'd up anything. Lots of distractions and I'm
trying to hurry and do other work.

Mike

Buy 'em books, send 'em to school, and all they want to do is eat

On my system (FreeBSD) with the Mozilla FireBird browser, the text and images are in light-colored windows inside the dark background, and it's not at all difficult to read. The Netscape 4.6 browser on the same system _does_ put the black text directly on the dark-blue background, and it is decidedly unpleasant.

A newer browser might be nice, but it also would be good if web page designers built pages with older code in mind.

It _definitely_ has some cool stuff. Thanks, Scott!

It's too bad it isn't that simple.

A 1V/m field doesn't result in one volt at the feedpoint of a perfectly matched one meter dipole or monopole, and the value it does induce depends on the quality of the impedance match as well as the fraction of a wavelength the one meter antenna length represents. And, if one volt does appear at the feedpoint, it's very unlikely that a simple circuit will measure it as one volt.

Probably best to stick with your $1.5 kilobuck meter if you really want to measure field strength.

Roy Lewallen, W7EL

Suppose you mean greater Cmax/Cmin, larger delta C was already
achieved above, but as you say "it doesn't work"
The tuning range can be calculated as follows:
(Cmax/Cmin)^2 = Fmax/Fmin

>If you use the

> a wavelength the one meter antenna length represents.

amplify, very please. por favor. Refresh my ram.

| E(uV/m) |
V (dBmV) = 20log | --------- / 1000 |
| 0.021f(MHz) |

plus correction for distance (regulations for limits are for
specific measuring distances), etc. I'll mull the above eq over.
Gotta figure out where the .021 came from, but not now. My eyes are
getting fatigued from this 'puter.

> And, if one volt
> does appear at the feedpoint, it's very unlikely that a simple circuit
> will measure it as one volt.

It would have to be calibrated to compensate for the circuit. Maybe
that's why it's called a "relative" field strength meter. Relative
to another signal or no signal ;)

>
> Probably best to stick with your $1.5 kilobuck meter if you really want
> to measure field strength.

I don't. He does :) At least not tonight. But my SLM *will* measure
field strenth using a cheap ass dipole cut to the frequency of
interest with or without an external preamp and do it to the
satisfaction of the FCC, assuming it's calibrated. I even have a
near-field probe, not so cheap. It beats guess work.

I wouldn't expect his sniffer to be real accurate but he did ask
for guesstimates. Started off as "around 4 feet" for a half watter
now we're at 100mW - prob his reference Tx.

BRs,
Mike

With a small flat mirror and light source they can become an
opaque projector...they kind used in classrooms and meetings
of not so long ago when the speaker could point to the paper
being projected.

With a high-intensity spot lamp, they can be a background "fill"
or "color wash" for outdoor Christmas decorations.

...or, collect a bunch of them and resell them, saving profits for a
wide-screen plasma screen TV. :-)

I have several other browsers, but I prefer using Netscape 4.79. Some websites are a royal pain. I recently ran into an electronics distributor who put their entire website in "Flash". There is no way I will wait five minutes or more per page to download and run stupid animation when I am looking for parts. I have seen a bunch of sites with a white background and a very pale yellow text.

My website isn't perfect, but I but a lot of work into making it easy to use and I asked for, and used, feedback from members of a couple newsgroups. You can see it at:
http://home.earthlink.net/~mike.terrell/ I still have a lot of work to do to the site, but a website is never really finished, is it?

With respect to the nifty digital displays these days. Describe your
preference.
For example, 14.295.55 or 14.295 55 or 14.29555 the other options are half
height
for hundreds and tens.

I personally like the format of one decimal and then half height for tens
and hundreds.
What do you like?

I don't suppose theirs someone/somewhere in the UK that sells these as surplus is their ?

They sound useful for using in a long range IR/Laser link (though I'd also need a small diverging lens for the laser).

>
>:) ! Adjust the meter to get the answer you want. Ok.

Yes! I'm only interested in *relative* field strength. That's why I
asked for a "ballpark figure" to be plucked from the air. I think you
may be thinking of some fancy type of instrument like some guy
mentioned he had that cost 1500 bux. These ham-type jobs I'm
interested in cost just pennies to make as they don't need any
absolute standard of accuracy; only a relative indication. You tweak
the meter's sensitivity control to show antenna A of the TX giving
rise to say S5 on the meter. You then change to antenna B and see if
the reading is any higher or lower. It's really as simple as that.

>I'll use a distance of 6m.

Noted, thanks.

My first regen RX was in 1947 with an A415 direct filament triode. (Does anyone remember it?) It was followed by DC11 - a steel 1.5 V filament tube - both excellent ones for regen receivers. (We used to call them Audions.) Bruce says there are three types of regens : with tubes, with FETs and with bipolar transistors. There is also a forth type: a negative resistance reganeration receiver, an invention of mine (also known as Lambda receiver). You can find its scematic in the British QRP Club's magazine SPRAT: number 111, page 4 - with a correction in number 112, page 25, and a complete construction in SPRAT 113, page 17 - with a correction in SPRAT 114, page 24. The schematic is a simulation of a tunnel diode and works in the negative part of the U/I characteristic. It does not have a feedback coil, and the regeneration is very soft - so the worst problem has been solved. Its stability is not convenient for CW or SSB, but it is excellent for broadcast stations from 500 kHz to 30 MHz; a real project for beginners. If someone duplicates it, I will be happy to hear about his experience - by e-mail (bozidar.pasaric@ri.hinet. hr) or on this group. Best wishes,
Bozidar, 9A2HL

> approach.

I built my first regenerative receiver in 1947 with an A415 direct filament tube, followed by one with a steel DC11 - 1,5 V direct filament tube - both excellent ones for the purpose. (Does anyone remember them?). Bruce says there are three types of regen receivers: the tube ones, the ones with a FET, and the ones with bipolar transistors. However, there is also a fourth one: the negative resistance reganerative receiver, known also as a Lambda receiver . The oscillator is a transistor immitation of the tunnel diode, and the negative resistance substitutes the feedback coil. It is my own construction. You can find its schematic in the British QRP Club magazine SPRAT No. 111, page 4 (with a correction in No. 112, page 25). The whole construction with a PCB has been published in SPRAT No. 113, page 17 (with a correction in SPRAT 114, page 24). The RX does not have a feedback coil, and the regeneration is very smooth and rather even over the whole band. So, that problem has been solved for good. It is not stable enough for CW or SSB, but it is excellent for AM broadcast stations from 500 kHz up to 30 MHz (with corresponding coils, of course). So, according to my opinion, it is excellent for beginners because they do not have to bother with the feedback coils.

If anyone would care to duplicate it, I would appreciate it very much if I could hear about his experiences with it (on this group or by e-mail: bozidar.pasaric@ri.hinet.hr). The whole project is still open for experimentation. Best wishes,

Bozidar, 9A2HL

Yup. gave you the eqs to figure out your ballpark figure. I figured
a ballpark figure might work if you gould figure out how much
voltage appeared at your RFSM antenna. had I known you had a
reference transmitter i might have suggested checking your RFSM
reading at one location with the ref and another closer location
with the test Tx, identical readings indicating sucess or close to
it.

Just curious, but would carrying out comparative measurements at say
only 6 to 10 feet give rise to invalid readings??

Lots of things can foul you up.

I think I estimated the near field/far-field at 3.7m so I wouldn't
do it. IIRC the change in field strengh with respect to distance in
one of the zones of the near field varies inversely with the cube
of the distance, as opposed to the square as it does in the far-
field.

BTW, I've seen other far-field eqs where the antenna diameter (not
aperature size) is used and I haven't bothered looking into the
origin, but I'm just trying to impress upon you the fact that
nothing's written in stone.

The 6m I gave as an example might not be all that great. These
short distances you mention have me thinking you're locked in a
dungeon somewhere so I tried to keep it reasonable. A sniffer might
be ok at close range and an active RFSM would be good at greater
distances.

Personally, since you've got a reference Tx, I'd take the whole
deal outside (they do let you out, don't they) and see what happens
with greater distances. Even a gym or auditorium would work if
you're concerned with how well it works indoors.

I remember the 40MHz part, but I'm not sure what yer up to. Just curious.

-mike

4294. Interfacing current driven differential output to voltage driven differential input

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-14 20:18:46 UTC
From: Sebastian Tombs <tombssebastian@hotmail.com>
Message-ID: <GA3Db.27783$ea%.19321@news01.bloor.is.net.cable.rogers.com>
Source record: 30161

Hi All,

I am trying to interface the output of an Analog Devices 9857 DDS modulator to a Maxim upconverter. The problem is that the output of the DDS is a current driven differential DAC, and the input to the upconverter is a voltage driven differential input. No problem, you say? But there is one...

The output of the DDS has spurs and aliases caused by the fact that this is a signal generated by the DAC from digital data. SInce I would rather not upconvert the spurs, etc. as well as the desired signal, I need to filter the output of the DAC. I want to keep the differential signal for noise-reduction purposes. The guy I spoke to at Maxim says that I must filter both arms of the DAC output before feeding the signal to the upconverter. Another alternative, of course, is to just connect the two with a shunt resistor and filter the upconverter output, but I would rather reduce the spurs as soon as possible rather than have them amplified on the board. Is there an efficient, elegant way to do this? And yes, I have also thought of taking the differential output, converting it to single ended, filtering it and then converting it back to differential...that's why I emphasize "elegant" above :)

Thanks in advance

<< my old bsr xl-1200 cartridge is wired onto the pins so it wont pop out with the 4 prongs as normal one's do >>

Louis-

I have an old cheap BSR changer that was sold by Radio Shack. It has slide-on terminals that connect to the cartridge pins. The cartridge is held in place by two screws. Are you sure your cartridge doesn't have slide-on terminals?

I also have an old Dual changer that uses a cartridge adapter. The adapter pops out when a "lift arm" is rotated. The original Shure cartridge is glued into the adapter, but it also has slide-on terminals. I believe it would ruin both the cartridge and the adapter, if I tried to separate the two.

I've had the Dual for about 25 years, but recall adapters that used cartridge mounting screws, were available for other cartridges. If BSR is still in business, perhaps they would have an adapter that is compatible with your turntable.

Fred

Yes. If it's not, either move closer, or add an op amp with
a gain control after the diode(s) & cap. Mine uses 2 gain
controls - 1 on the input to the op amp, and one that sets
the gain of the op amp. A further improvement is the use
of a cheap DPM - no parallax and a wider "full scale" range
with no loss of sensitivity. The downside of the cheap DPM
was the need for 2 9 volt batteries. (I have since built a
small DC-DC converter that occupies the volume of a single
9V battery. That may allow using a single rechargeable
9V to power the converter - but I haven't tried it yet
to be sure that the converter doesn't produce noise that
would be detected by the instrument. The converter does
produce dual 9V fully isolated outputs at at least 10 ma
per output, way more than the instrument needs.)

Like trying to accommodate fighting parents, having Micro$oft constantly extending and subverting standards.

> It _definitely_ has some cool stuff. Thanks, Scott!

Thanks. Any things you like more than others? When I make time, I plan on documenting my tinkering with windows html/hta app to md5 sign and test your pc files, laser-pointer velocimeter and interferometers, PIC hardware and software for alarm system, and micro-power radar sensors. I should update the bookmarks and clean all the dead-links too.

I'll add that my Optoelectronics handi-counter's fsm bargraph can detect a few hundred milliwatts at several feet away.

I visualize a radio-field power density being grid-lines painted on a balloon around a 1/2 wave dipole. As the balloon is blown up, the grid-line expand, given by 4 pi r^2.

For some good app notes on designing electrically small antennas and radio link calculations:

Goto -
http://www.rfm.com/corp/apnotes.htm

Checkout:
http://www.rfm.com/corp/appdata/antenna.pdf
http://www.rfm.com/products/tr_des24.pdf

HP (now Agilent) has some app-notes on designing diode detectors, and has some utility programs that will help you design and calculate performance. Some I think, in context of RFID reading devices. But they point out you get a square-law for small signals, which gets nonlinear for larger signal levels. And what bias the detector diode has on it.

Sorry. The next time I update it I'll see if I can find a better color.
I think I noticed that once while I was developing it - I think it is
due to a low-color VGA mode. I spent too long fooling around trying to
develop the fractal-smith chart background (thanks to da GIMP) to mess
with it any further. You can always edit the HTML yourself and change my
background color. Its not like I've got advertisers paying me.

Does anyone know how common 10.7MHz oscillator crystals are and where I can get them, preferable in Canada.

The reason, I've decided to build a 21MHz xcvr and the 10.7MHz crystal, when multiplied by 2 is at 21.4MHz which is at the top end of that band. The 10.7MHz crystal will be running the LO (obviously).

TIA

Nope. *All* the 40Mhz stuff I post about is 'bot related. That's the
r/c band we're permitted to use. There's an alternative option to use
something up in UHF but I'm giving that a miss for obvious reasons.

you'd shit if you knew how easy it can be to do a UHF radio with an
RFIC, but I'm not sure you're permitted to use the same modulation
methods. Hell, you can get a pre-approved module for $100. FSK -
you can use that! isn't you're deal PPM FSK? or PCM FSK?

actually, I've changed my design. I'm going to go with a direct conversion reciever instead of building a heterodyne reciever this time around. It's a lot simpler and smaller to build and will be a good refresher for 2-way. (It's been about 4 years since I touched a radio.)

<< i think i could remove the wires
and put each one onto the prongs of a new cartridge but it seems that
the bsr cartridge is proprietary. there is one screw on top of the
tone arm that holds my cartridge. i'm not sure it will screw into a
new one such as the at3482u. >>

Louis-

I wonder if the single screw actually mounts an assembly consisting of the cartridge and a spring-clip that holds it? Have you disassembled it for close inspection?

From what you say, and observing my own changers, I don't think there is a "standard" method of attaching the cartridge. The closest I find, is that some cartridges are mounted with a screw on each side, through elongated holes so it can fit a variety of tone arms.

Looking closely at the cartridge near the terminals, you may find small letters L, R, LS, RS, indicating Left, Right, Left Shield and Right Shield. This should help you figure out how to wire a replacement cartridge if you can find one that fits.

I recently dug out my old Stereo equipment, hoping to restore it. Two out of three old changers no longer work reliably. The BSR was a cheap one from Radio Shack, and the needle skips several grooves when it is close to a speaker and a loud bass note is played. The best solution seemed to be to buy a new changer, but I find that none are available. The only thing I find is a simple, cheap turntable intended for disc jockeys to make scratching noises! Do you know of any recent High End changers or turntables?

>specific measuring distances), etc. I'll mull the above eq over.
>Gotta figure out where the .021 came from, but not now.

I use simplified formula for practical life with also some antenna
mismatchings & soft obstacles in-calculated:

dBm = ~90dB x 1Mhz x 1km or better dBm = 100dB x 1Mhz x 1km
for having better Rx SINAD

since voltage on Rx antenna drops linearly with rising a frequency &
distance & vice-versa. From dBm´s got I just recalculate RX voltage on
RX input

simple & effective calculation IMHO ...

Picked up this Used FC-1000 Automatic Long Wire Tuner and need some coaching.

The Yaesu FC-1000 Automatic Long Wire Tuner was designed to be used with the FT-747GX/ FT-757GX Series Transceivers in that the Freq being used is fed to the Tuner via a cable.

Has anyone had any experience useing this tuner "Stand Alone" without the "matching" Transceiver feeding Freq Data to it? OR has any more Technical Info on its operation? I would like to try to use the tuner with other Transceivers

I am sure there were a number of these units sold into Amateur Service and/or Marine use.
I am presently using an FT-100D with ATAS-120 Screwdriver in my Explorer.

I have the manaul with schematics, and will probably find the answers to my questions EVENTUALLY...just looking to speed up the process ! !

Thank You for any replies

The butler type is a tuned amplifier were there is ideally zero phase
across the crystal and hence the crystal can be simulated by a resistor
of equal (in practise lower) resistance than the crystal loss.
Hence a butler tuned to 100MHz will oscillate a 50R resistor at that
frequency.
The 100MHZ crystal if 5th overtone will have a fundamental response at

approx. 20MHz and a 3rd overtone response at 60MHz .
The fundamental response (resistance) will be much lower than the 5th
resistance and in a zero phase amplifier with flat response the crystal
will preferentially oscillate at 20MHz.
Higher order overtones have the same C0 or stray capacitance as the
fundamental but this has a lower reactance at higher frequencies.
This is the reason and increase in resistance at higher overtones that
overtone oscillators get increasingly tricky.

Thanks everyone for the interesting and useful information.

For the record, I am not particularly in love with tubes, but if there is something they will do better than solid state devices I'm willing to give it a try. When I can buy PN2222 bipolars for $.02ea and PN4416 JFETS two for a quarter, and dual gate MOSFETS for a nickel, the expenditure for one of those fragile glass things better be well worth it. It can' be different or just a little better. It has to be "knock your socks off" superior...I make radio kits for kids and schools and I want them to be able to afford the purchase.

People here have recently mentioned tubes intended for portable operation, with plate voltages of around 20 volts. Much more common are tubes intended for running from mains-powered supplies. These mostly require plate voltages that can be lethal. You should consider this when designing kits for kids.

Source record: 30199

Need Help with my Kenwood TM-741A Triband FM Mobile Radio.....I purchased the radio new some 12 years ago, with the 220MHz. Module Installed....The Radio Has 144 Mhz / 220Mhz / 440 Mhz.....For years the radio worked excellent....Then about 5 years ago I had lost the out put on 144 (two meters)... However , the other two bands functioned fine...220/440mhz... I sent the radio back to kenwood...and they indicated that the Driver Transistor Q23 2SD1902R on the two meter module was defective. This transistor is an inexpensive part...$ 3.05 ea. Anyway...It seems like the same problem occured the other day...all the symptoms seem the same...Can anyone shed some light on why this seems to happen often?? Also is it possible to replace this 2SD1902R transister with something capable of handling some what more power dissapation?? What ever happened to those motorola hep sustatutes?? Any and all info supplied here will be greatly appreciated....

Thanks
Carl

The 40673 as I recall was a dual gate FET. Used in mixers and other stuff
dual gates were used. They were in a small metal package (TO-??) with 4 leads.
I think I remember their orginal application was CB xcvrs.

I though Agilent made you answer a bunch of questions before they would let you at their stuff. Doing a web search on one of the app notes I downloaded, I get:
http://rf.rfglobalnet.com/library/ApplicationNotes/files/1/An1089.pdf

RF Globalnet's got lots of good stuff. Probably where I got the design apps from too.

HP app notes I collected:

pin diode pi atten an1048
pin diode switch an1049
x-band mixer an1052
pin diode freq mult. an1054
(comb gen)
pin diode t/r switch an1067

For starters, Heathkit used them for their dip meters. There are a lot of uses for this mosfet, and I am afraid they are scarce!! I have 20 of them right now and I think I might be able to get more, but I am not sure. If anyone is serious about this, I will sell this lot for $40.00 , so e-mail me. Rob WB8VWI

Motorola dropped the HEP line at least 15 years ago. So did GE,
Workman, and several other replacement lines. ECG was recently bought by
NTE, the sole survivor of the universal semi replacement business.
http://www.nteinc.com/ has a downloadable database for finding
replacement parts. There is no cross reference for this part, but you
can check their on line parts search to see if it has recently been
added.

main arguments are right, but I don't believe the frequency scheme is
right. If 20MHz is the fundamental, it doesn't make sense to tune the
2nd circuit to 100MHz, you could tune the 1st. You could also operate
the first tuned circuit at 60MHz and have o/p at 120 or 180MHz, with
sub-harmonics of n.order 60MHz.

It was a tendency 20 years ago to apply overtone xo's running at
150-200MHz, but they very soon dissappeared because of too much
instability problems

Sorry for the slow response.

The voltage at the terminals of a short, lossless dipole of length l which is perfectly terminated with the complex conjugate of its feedpoint impedance is E * l / 2 where E is the impinging field in volts per meter. Any mismatch lowers this value -- it's one of those valid and useful applications of the concept of "mismatch loss", which can be used to quantify the reduction when mismatched. It's one of the contributions to the extensive variation with frequency of the "antenna factor"(*) of test dipoles used in EMI work. (And careful measurement of this factor is a large fraction of what you're paying for when you purchase one.) Doesn't matter how wonderful your field strength meter is unless you have a very good handle on the "antenna factor" of the test antenna.

In simple terms, the factor of 1/2 is the ratio of the average current to the feedpoint current. The average current along a short dipole is about 1/2 the current at the feedpoint. You could get a factor of 1 if you used a short dipole with large end hats to make the current distribution uniform. Kraus addresses this case in detail in _Antennas_.

And no, I don't mean "antenna to free space" match. I mean the match between the antenna feedpoint as a source and the detector as a load.

(*) Ratio of output voltage when terminated in 50 ohms to the impinging field in volts/meter.

Take a look at http://www.tubesandmore.com - Select "books" and enter
"regen" in the search field. You will find at leat ten hits, all with books
full of diagrams and drawings. Cheap, too!

I'll dig into the Antenna Engrs Handbook.

I guess we've been lucky. So far no FCC gigs on leakage. Haven't
heard about anyone failing a flyover either. Maybe the systems
consider the FCC spec and set their spec to account for cheap-assed
dipoles. If so, that's smart and I'd be surprised. Some day I'll
check that out.

That's a given. I figure Paul already knows that.

The regens I built as a youth were always just one triode [0-1-0 in the old description code]. They were for the AM broadcast band. Fine with high impedance earphones. You'd want at least an audio cathode follower to drive today's low impedance phones. [0-1-1 description]

Too bad I burnt out so many UV99, UCX99, WD11, 01A, etc, tubes. One wasn't too sharp at electronics at age 12 or 13, & probably a bit clumsy w/ the fingers.

<< I think I remember the number from the dlate 1960s but can't recall what their main use was, refreesher? >>

Hank-

The RCA 40673 Dual Gate MOSFET was used as a low noise VHF RF Preamp in the early 1970s. There were at least two preamp kits popular at the time, such as the one from Topeka FM & Engineering. I used such a preamp on my Regency HR-2A, supposedly improving the sensitivity from 0.35 uV to 0.2 uV. Of course there was an increase in intermodulation interference that came with it!

While there are many such pieces of equipment still in use, there are newer devices that can be used as a replacement for the 40673. An example (only slightly newer) is the 3N201.

Today's FM rigs typically have better sensitivity even without an additional preamplifier.

I'm building a kit that Ramsey doesn't sell any longer. I recently read the QST equipment review on this radio and found that Ramsey used to provide a mod kit to eliminate spurious emissions. Ramsey no longer has that kit and doesn't seem to have any information about the components or circuit modifications. I've already checked the typical mod sites. Anyone have any ideas?

<< I sent the radio back to kenwood...and they indicated that the Driver Transistor Q23 2SD1902R on the two meter module was defective. This transistor is an inexpensive part...$ 3.05 ea. Anyway...It seems like the same problem occured the other day...all the symptoms seem the same...Can anyone shed some light on why this seems to happen often?? >>

Carl-

As far as I know, the Band Units are the same in the TM-742A. I recently had my Two Meter Unit to fail, but it wasn't a single transistor - it was the SAV17 Power Amplifier Module. It cost $54.95 from RFParts Company, the Kenwood parts supplier.

It may be possible to remove the cover of the PA Module, and replace individual components, but that was more than I wanted to tackle. I suspect that Kenwood wouldn't do that either, since labor costs could exceed the price of a replacement.

The 2003 RFParts catalog lists a 2SD1902 for $1.50. I don't know how that differs from the 2SD1902R.

I have succesfully set up a program to read and write values based on the operating manuel. I would like to be able to read and write memory channels though which are much easier to setup on a computer screen then through the radio, especially considering naming of the channels. Does anyone know the communication sequence when the radio is in cloning mode. I have seen programs like FTBasic read from the radio using this method. I would like to provide a program free to hams in my area. I am not willing to pay $30 just to read and write memory channels, when I know I can write a nice interface to do it. I just need the communication protocals for sending and receiving in cloning mode. any help would be much appreciated.

That's not really a surprise. It's always been a constant that
a handful of parts are used in the magazines. By sticking to
a few parts, it guarantees that you will be able to get those
parts, since small companies that deal with the hobbyist will
carry those parts. And then in turn it guarantees that the
parts will be used.

Besides, many articles were traditionaly a variant on something
that had already been published. So someone looks in the magazines,
and picks parts (or even whole circuits) based on what they see,
and then write about it.

I've always tended to look at those common parts as a designator
for a generic category of something. So a 40673 is a dual gate
MOSFET, and likely some other similar part will fit the situation.
After all, if someone was going for extreme performance, it would
not be a common part.

I'd say get rid of that piece of junk and get the Tentec 2 meter radio kit,
I built the 6 meter version and it went together like a charm.

Someone here locally had the Ramsey 440 kit, and after building it and
finding that it wouldn't work found out that the design was flawed from the
start and it could never work.
thanks, John.

Here's something that might be fun to try on a regen or most any
other tuning circuit, a rebirth of the old reactance modulator circuit
to change the parallel capacity across a coil. For 190 KHz band-
width at about 6.1 MHz, this 3N200 dual-gate MOSFET add-on
claims linear-frequency tuning from a potentiometer. That's a bit
like the old "bandspread" tuning of prehistoric times. :-)

From EDN, 5 November 1998, Design Ideas Section, pp 130, 131,
Last idea entitled "Tube" Circuit Provides Linear Tuning. [came
across that one while searching for something else...]

On the Internet at http://www.reed-electronics.com/ednmag/archive/

Select year, then issue date in that year. A table of contents comes
up and scroll down to Design Ideas. Clicking on any Design Idea will
bring up the whole section in HTML. At the top of the HTML first
page is a box for a PDF of the same thing.

EDN has archives back to 1994 if anyone wants to peruse them or get
a copy of an older article.

The guy with the flash camera idea is on track. Audio Express Magazine had a writeup on them a few months ago, as did Nuts and Volts some years back. I reverse engr'd a Fuji camera and it's just like the AE Mag circuit.

Circa 1976, I made a simple two transistor oscillator, which ran off a 1.5 volt battery that connected across a reversed filament transformer, lite a neon bulb for weeks. I'm sure it would really honk with 9 volts DC chop input.

cheers
skipp

I have the following tubes;

6SC7
6SL7
6SN7
5Y3
8552

Is there any transmitters or receivers that can be built with these?
If not TXor RX, what can be done with them?

But I did build and test an FX-440. It can work but not very
well. If you ever hear one on the air, listen to how higher the
background noise on the modulation is, the result of using a fairly
noisy op-amp audio chain to directly modulate a VCO with a
sensitivity of like 10MHz/1V... It's no better than a toy.

Good luck.

Dana

Hm.... this should be on the Extra exam :)

6SC7: VFO
6SN7: transmitter final
5Y3: Power supply rectifier
6SL7: 1-tube regen

8552: damfino!

I'd say you could build a very primitive transciever.

Others have mentioned uses for these tubes. What they haven't mentioned is that you will need a power supply delivering DC somewhere in the 150 to 250 volt range. It is absolutely vital that this supply have a transformer to isolate you from the 115 V AC mains. Otherwise you'll likely kill someone or yourself, since on side of the AC line is connected to ground and the other is HOT with respect to every grounded object.

Junk boxes all across the world may be full of these transformers, but you may have trouble finding one. In that case you could use a couple of 115 to 12-or-so volt transformers. One to go from 115 to 12 V AC, the other connected "backwards" to go from 12 V AC back to 115 V AC. Now you have 115 V AC with neither side grounded - much safer.

Just to add, if you only need ~15 watts for your project, bathroom shaver isolation transformers hooked up in a FW doubler are great for this too.

You can get them from building surplus or second hand stores for 2-$5.

Hi all,

I have a Weller WTCPS soldering station with a 201U power supply and 201P iron, using a 700 degree F tip. Last night I powered it up in preparation for soldering some connectors, and a few minutes later I saw that the tip and metal shaft of the iron were glowing red-hot.

Any ideas as to what is causing this, and will it be cheap to fix? Are there any checks I can do to diagnose the problem? Or should I just dump the thing and buy a new one? I bought the station over 11 years ago, in practically new condition, at a yard sale for $5, so I got my money out of it, but if a reliable fix is cheaper than purchasing a new soldering setup I'd rather go that route.

Thanks!

-Josh, AE6IQ

Weller sells, through distributors, replacement parts. I suggest that
you replace the temp-sensing tip element, as a start.

I would guess that the fault lies in the iron, not in the station base.

If I recall correctly, the station base is simply a stepdown
transformer. It plays no part at all in the temperature regulation.

The temperature is regulated via a rather elegant (I think)
implementation in the iron. At the base of each tip, there's a slug
of a ferromagnetic material. The properties of this slug are
controlled during manufacture, so that it will change from a magnetic
to a nonmagnetic state at a specific temperature (e.g. 700 F).

Inside the shaft of the iron there is a switch with a magnet on the
end. When the tip is below its transition temperature, the magnet is
attracted to the ferromagnetic slug on the back of the tip, the switch
is pulled forwards, the contacts close, and current flows through the
iron's heating coils. When the tip reaches its desired temperature
the ferromagnetic slug becomes non-magnetic, the magnet in the shaft
"loses its grip", the switch is pulled backwards by a spring, the
contacts open, and the current to the heating coil is interrupted.
You can hear (and feel) a gentle "thick" when the magnet switch pops
back and forth.

It's a nice negative-feedback system. It allows the use of a rather
high-amperage heating coil and transformer (which can heat up the tip
quickly when powered on, and restore heat taken out of the tip by the
soldering process), and yet allows any of several temperature ranges
to be selected by changing the tip. It seems to be quite robust...
I've heard very few reports of failure.

It seems that you have a failure. I would guess that the switch has
failed... either it's become jammed, or the spring has broken due to
metal fatigue. [It's possible that the ferromagnetic slug has somehow
magically changed its properties and now has a transition temperature
several hundred degrees higher, but that seems _very_ unlikely to me!]
In any case, the heating coils are running full-time - you've got no
temperature regulation - because the switch isn't opening.

> Are
>there any checks I can do to diagnose the problem? Or should I just dump
>the thing and buy a new one?

You can probably replace the switch (or, worst case, the whole
iron-and-handle assembly) for rather less than the cost of a new
station. The transformer and line cord, and whatever tips you may
have purchased, are almost certainly OK.

It might be worth disassembling the iron, and seeing if a sharp "rap"
on the side of the iron shaft will dislodge the switch.

If not, you could check with Weller to find out about getting a
replacement switch. The current incarnation of this product is the
WTCPT, using a TC201T iron. Mouser sells the complete TC201T iron for
around $72 (roughly half their cost for the whole station). The SW60
switch for this iron sells for around $26 - you'd probably need to
check with Weller to confirm that this switch is the same one used
in (or is compatible with) your older 201P iron.

$26 to restore this station to full life would be a very worthwhile
investment. I spent about $100 for a WTCPT iron close to 15 years ago
and have never regretted it. I used to go through cheap $15-$25 irons
every couple of years, through cheap tips a lot faster than that, and
I'd burn up components (or have difficulty getting a clean joint) and
cuss a lot. The WTCPT hasn't hiccoughed even once, and I have yet to
have to replace the original tip which came with it.

Agreed, had it happen myself. Not sure about the specific model but
ISTR the thermostat is in, and indivisible from, the element.

The "bit" has a lump of Iron with certain temperature chararistics (
peltier effect ?). When the temperature exceeds the Iron magnetic
ability the element switch, (with a magnet on the actuating arm),
drops out until the Iron, (this is the Iron on the bit), regains its
magnetic ability.
KISS in its best form. I have managed to "unstick" the magnet before
now, but its a bugger to do.
Sorry I can't describe the operation in a more scientific language,
but I'm sure someone will ba able to... ;-)

Hi there.

Another Amateur that is involved with volunteering with schools and such is looking at launching a baloon with an HF transmitter on board. The band of operation is 80 meters. He is looking at some type of a beacon that will send data via BPSK modulation and needs 10 to 20 watts of transmit power at the output port. For an input to the unit he has 0dBm or 1 milliwatt of RF at the operating frequency.

This looks like it would require 40 to 43 dB of gain to get to the level that he needs for output.

Does anyone have suggestions of places to look on the web for application notes and/or schematics for amplifiers along these lines?

I have done some searching on Google and found a few things but most of them take inputs of 30dBm or so and only take that level up to 40dBm. He still needs to bridge the gap from 0 dBm to 30 dBm in that instance.

Any information that you can help with is greatly appreciated.

Al Butler

>the same thing?

Probably so. A material's Curie point (or temperature) is the
temperature at which, when heated, the material ceases to be able to
support/retain a magnetic field, and any existing magnetic field is
randomized.

Heating a permanent magnet above its Curie temperature demagnetizes it.

The slugs used in the Weller tips have Curie temperatures of 600, 700,
or 800 degrees F (plus or minus a bit, I imagine).

Hmmm. Seems to me that many of the VFO-and-mixer QRP CW/SSB
transmitter projects might have suitable designs... a few milliwatts
out of the mixer and bandpass filter, into a one- or two-gain-stage
driver which would then push power out to the final transistor(s).

Let's see. The Small Wonder Labs PSK-20 transmitters seem like a good
place to start looking. The schematic shows that the transmit
circuitry uses a Minicircuits TUF-1 mixer. According to the
Minicircuits web page, this takes as input a +7 dBm local oscillator
and up to 1 dBm of RF. It has a conversion loss in the 7-8 dBm range,
so you'd end up with somewhere around -6 dBm at most coming out of it.
The PSK-20 transmitter buffers this through a transistor, then through
a MAR-35M monolithic amplifier, and then through a 2SC1970 and
2SC1971, and ends up with 2.5 watts of power.

Seems to me that you could probably fiddle with this final stage a bit
(double up on the 2SC1971, heatsink 'em, run at a higher current
level, and adjust the driver circuitry to suit) and end up with 10
watts out.

One more idea -- the old mass-produced geiger counters now available cheaply on eBay have very simple HV supply circuits that use minimal components, and run from 1.5 to 6 or so volts, depending on the model. They come with a schematic and parts list. Although the parts are just about all obsolete, you could find modern substitutes that would work.

Photoflash units typically keep oscillating and drawing power even when the cap is charged, but if you arrange to turn one really OFF most of the time, the average current could be very low. You just need a cap that will hold the charge well. Polypropylenes are known to do a very good job in that respect, but in any event the reverse leakage of the rectifier diode is likely to dominate. It's possible to come up with ridiculously low reverse leakage rectifiers if it's an issue.

Because of the low current required, it's worth thinking about using a voltage multiplier. A simple blocking oscillator (transformer and transistor) with even just 5:1 stepup to the secondary, then some voltage multiplication, should do it.

You didn't mention regulation: the mic sensitivity will generally be proportional to the bias voltage, so some regulation is probably appropriate.

Another possibility: a stack of 60 or so lithium coin cells. Quiet, good voltage stability, ten year life. At about 40 cents each from DigiKey, the $25 cost is probably less than you do an 'lectronic solution if your time is worth anything. Can be packaged into a cylinder about an inch in diameter and four inches long. (PVC pipe + fittings + small spring?) Completely isolated: no possible ground loops. No oscillator to generate noise.

Cheers,
Tom

Shouldn't be too difficult to come up with the brute-force answer, but
I have to ask: Why?

That is, why so much power? And why 80 meters? I'd think you'd want
to use a higher frequency so that the antenna would be easier, and if
the balloon is aloft and line-of-sight, even a watt should be more
than enough to hear it loud-and-clear. Sending up an amplifier and a
power plant that will run it at 10 watts output will take quite a bit
of balloon displacement. I think it may be worth asking some
system-design questions to see if he can reach a more optimal
solution.

Cheers,
Tom

Greetings.

I have a pixie 2 xcvr currently set for 80m. I have been wanting to put it on the 20m band, so I found that I require a .551uH.

I assume that this would be a terribly easy coil to wind, but I've never wound a coil w/ intention of achieving a specific inductance. If anyone is familiar w/ the number of turns/gauge etc... for a .551uH inductor, I would really appreciate that info.

Thanks much.

a .551uH inductor, I would
> really appreciate that info.

Use the following formula:

$$L(uh) = \frac{(N^2)*(R^2)}{(9*R)+(10*L)}$$

L(uh) - Inductance in microhenries
N - Number of turns
R - Radius of single layer coil in inches
L - Length of single layer coil in inches

If the coil is just for RX then you can get away
with using 22 to 24 gage magnet wire. Be sure to
use a coil form to wind the wire on. Then cover
the coil with coil dope, or other material, to
hold the turns in place. That will keep the coil
inductance stable.

Pick a convenient coil form size and just plug in
some numbers, using a spread sheet, until you find
a set of coil dimentions that you like.

Look in the ARRL Handbook, under calculating practical inductors. For a .5uH inductor I would try as a start, a 1/4" drill bit wound with #20 or #22 solid, with the length and turns / inch per the Handbook formula.
If you don't have the Handbook, I can post the formula, until you can get a Handbook :-).

Looking at the Dave Benson schematics is a good suggestion ... I would also look at Elecraft who also has manuals online with schematics. I would also look at the hfpacker amp (www.hfprojects.com). This was a project ran a couple years ago to build an amp to basically take the QRP rigs in the 2.5 watt range to 30 watts or so. The design actually could do it with a watt of drive but they put an attenuator in the front to allow flexibility with different rigs that didn't have completely adjustable output power.

But I also have to ask the same question Tom asks. 80 is a noisy band, and one that demands large antennas. To get past the noise you need power, and that adds a lot of weight. Don't forget, you not only have the amp to carry around, but you gotta carry the DC to run all this, too.

If you are line of sight, then you can go very high in frequency, but certainly in the higher parts of the HF spectrum, the antennas are more manageable and the bands are quieter, which means power is less of an issue. You could even go to VHF but then the whole construction thing becomes more challenging.

But then, if you are looking for a 100-200 mile path, then 80 probably is the ticket, but you're going to have to constrain your playing to days when the A index is low. Indeed, I would suspect you would want to be balooning in the daylight - precisely when 80 is very noisy. So you better be paying close attention to the propagation reports if you want to hear your baloon.

It is VERY EASY to fix / repair the Weller WTCP units.

First, Are you positive you have the CORRECT TIP in this iron.

It MUST BE A Weller "PT" style tip - other Weller model tips such as the ET series will cause this problem and damage the iron.

Josh -

Let's deal with your problem and Facts.

The WTCP series base only provides 24 volts - that's it - its a transformer
in a base.
The "brains" of the temperature control is the tip working in concert with
the SW60 switch assembly
The WTCP series has a unique click as the SW60 switch engages and
disengages - turning the heater on and off to maintain
the specific temperature engraved on the base of the removal tip.

The Red-Glow tells you 2 things:

1. The heater (Weller EC234) is still working (but you are shortening its
life operating in this manner - cherry red)
2. The WTCP series temperature control (which works with the "PT" tip and
the SW60 switch) is not working properly.

Recommend: Change tips. Improper tips will cause this problem.
Get a Weller PTA7 (which is the standard tip shipped with this iron).
The barrel net (BA-60 may also require replacement.

If iron exhibits identical problem - then the SW60 requires replacement
(shorted closed).

All parts for this specific model (WTCPS) are available from Wessco (So. California).
Wessco also just ended a 1/2 price sale on Weller "PT" series tip in November ($ 2.25 each)

I also have the Weller Tech Sheet for this model -- if you need a copy. This has part numbers, diagrams and troubleshooting advice (shipped with every unit new)

Yes, I will consider repairing for you - but it would have to be after the holidays.
Greg
Repairing the Weller WTCP series since 1975

James,

Try this easy way to make .55 microhenry coil:

Take a 1/2 watt resistor of about 1 meg ohm or more in resistance
(value irrevelant, just make sure it is above about a megohm),
put a tiny notch near one end parallel to the leads of the
resistor just large enough for 28 gauge wire to sit in (I use
a small pocket knife or a :Swiss file" whichever is closest at
hand when I wind a coil), solder a length of 28 gauge wire to
one of the resistor leads very close to the body of the resistor.

Now wind 15 1/2 turns of the #28 wire around the body of the resistor
and make a similar notch on the other end of the resistor and solder
the free end of the wire to that lead like you did the first. Keep the
turns touching each other ("closewound".)

Cut off the extra #28 wire and use this homemade .55 microhenry coil
in good health. It may or may not be EXACTLY .551 microhenries,
but it will be pretty close. The calculations come from a BASIC
program published in 73 Magazine years (decades?) ago and seems to
work pretty well.

Good look and post a report of how well this project goes.

Sorry if I made the explanation too simple if you already wind a lot of
coils, but I sometimes get carried away (gets worse the older I get...)

73,

Phil - N4GWV

Dunno how accurate you need it to be "as wound", and dunno what sort
of form factor you want, but if an air-core coil will work for you,
here's one way: get about 18 inches of 18AWG wire, nice and straight,
and a 1/2"x13TPI bolt. Wind 11 turns of that wire into the threads of
the bolt, leaving 1" of wire on either end (or start with a longer
piece if you want longer leads), and unscrew the bolt. The result
should be a coil about 0.85 inches long and 0.424" ID, and 0.600uH.
When you get it mounted near other things, the inductance will go down
a bit, and you can adjust it down further by stretching it a bit. The
Q at 14MHz should be just over 200. Or you can use 10 turns of 16AWG,
done the same way, which will have a slightly larger ID, 0.434 inches,
and about 0.561uH nominal and very slightly higher Q.

In general, the L = (n*r)^2/(9*r+10*l) formula works well, where r and
l are radius and length in inches, n is number of turns, and the
inductance, L, is in uH. My numbers above come from a program that's
easy to use and that I've learned to trust from verified results.
It's convenient to use a bolt to get consistent spacing and diameter,
though for high stability, you'd want some sort of support. For
highest Q in a given volume, go for a coil with roughly equal length
and diameter, though that's not terribly critical.

Cheers,
Tom

I was a little distracted by the main path of the conversation that we were having so I didn't ask at that time why they wanted 80 meters for a beacon from that high. I also realize that it is going to take a fair amount of battery to keep this thing going for any period of time.

These people do a lot with GPS. Maybe they are hoping to pass GPS location data to the ground crew after the payload lands so that they can go right to it and pick it up. I have no idea what they are doing with antenna ideas or anything like that.

Now, what was his phone number? :-)

In the mean time thanks for the information. I will get to looking at it and pass it on.

wrote:

>Weller sells, through distributors, replacement parts. I suggest that
>you replace the temp-sensing tip element, as a start.

The only heat sensing element in the WTCP? series is the lump of metal at the tail end of the tip. The correct tips for this iron will have a separate bit there with a single digit stamped in it. That's normally a 7, for 700 degrees F.

The alloy of this lump is chosen to have a Curie temp of 700F and it will never change.

There is a magnet that runs down toward the tip and is attracted to the tip when the tip is below its Curie point. Once the temp reaches the Curie temp the lump no longer attracts the magnet and the magnet is pulled back upwards by a small spring. This opens a switch in the handle and turns off the heating element.

The usual problems with these are that something gets inside the sleeve behind the tip and jams the magnet so it can no longer move, or the switch contacts weld closed.

With the iron off and cold you can remove the tip retaining sleeve. When you pull the tip out you should feel the pull of the magnet and then feel the switch and magnet snap back into the barrel once the tip is too far away to attract the magnet. You should repeat this to verify that the magnet is free to move.

If you unplug the iron from the base and put an Ohmmeter on the pins of the iron, you should see the continuity come and go as you take the pin in and out.

Weller is owned by Cooper Tools and PDF files of replacement parts are available on their web site.

Hello everyone,

My wife and I had been 'discussing' some of the effects of my hobby, such as the possible exposure of my 2-month old baby girl to lead vapor from soldering.
I typically have been using coventional 2% silver electronics solder wire with
my 12 watt pencil. I do a few connections every day, but my wife wants to take absolutely no chances, and on reflection, I don't really want to either.

I'd like to know if here is anyone in the homebrew community who uses lead-free solder for fine electronics work, what brands or compositions they recommend, and where such can be obtained retail for a reasonable cost.

Oh, yes, and can someone lend me a yard of it until I can afford my own large spool?

Thanks in advance,

The Eternal Squire

Mike -

Sounds like I will have to get the scanner (for Acrobat Reader creation)
warned up this weekend - :-)

The Weller Tech Sheets (WTCP/ WTCPL; WTCPN; WTCPS and WTCPL) were available
directly from Weller (free) --
but have not asked for them --- since the factory was moved from the
Carolinas to Mexico last year.

hmmm, I have recently had the same discussion with my XYL, we have a 1 yr old.

My self and another NASA trained ham, N9AEP, just completed teaching a soldering class for our ham club, Schaumburg Amateur Radio Club.

The EU is going to require all soldering to be Pb free in 2004, I believe that all US manufacturers will be required to do so in '06. I'm sure I'll be corrected on the dates.

Your note brings 3 comments to mind:

1. Please use a 35-50 watt iron for your soldering work. You want to heat the junction as quickly as possible and minimize the length of time that the joint is heated. In soldering 40w for 1 second is going to heat a component FAR less than 10w for 4 seconds. example your hand can deal with 600 degrees for 1 second but not 150 for 4, you would be scalded.

2. Flux in solder is organic. In most manufacturing situations the rosin flux is kept temperature controlled until use to preserve it. You want to buy the smallest quantity you can quickly use. Don't buy a large spool of solder and then store it for years. It is recommended that for maximum effect that the rosin be <6mths old. If you have to use old solder then buy a flux pen, this will greatly help the flow and adhesion of your joints.

3. Kester solder has a good repository of info, taken w/salt, at their site, www.kester.com. This includes alloy, melting point, application notes.

BTW, Pb vaporizes at 1749C or 3180.2F

Al -

You have 2 very large helpful balloon organizations (NSTAR) in the Omaha /
Kansas City corridor ....
using GPS, VHF (2 meters, 70 cm, etc.) with VERY favorable results.

80 meters is a poor choice for project -- and 20 to 30 watts will be a power
hog (weight)
that is counter intuitive with what is trying to be accomplished.

LOW WEIGHT and HIGH PERFORMANCE are your criteria.

Check out the NSTAR light weight camera -- sending video at UHF to ground !
(you can't do this with 80 meters)

NSTAR
http://www.nstar.org/

Edge of Space Sciences
http://www.eoss.org/ansrecap/ar_060/recap55.htm

RCKARA
http://www.rckara.org/project_traveler/2001a/

NSTAR 2004 Flight Schedule
Future Flights
Here's our flight schedule for 2004. Those without a listed location will be from our usual sites (near Treynor IA or west of Omaha NE).

a.. 04A - Mid to late February (SSTV scheduled)

b.. 04B - March 20 - Central Plains Severe Weather Symposium - Lincoln NE (SSTV scheduled)

c.. 04C - April 17 - Strategic Air and Space Museum Family Day - Ashland NE (SSTV scheduled)

d.. 04D - Mid to late May

e.. 04E - July 3 or 4 - Great Plains Super Launch - Hutchinson KS

f.. 04F - Mid to late August

g.. Perhaps 04G and 04H before the end of the year

You can check the Kester web site on the lead-free update
http://www.kester.com/leadfree_update.htm

Even without lead content, breathing flux fumes from solder can cause
respiratory irritation/problems.

Kester Recommendations
http://www.kester.com/recommendations_leadfree.htm

May I suggest a fume-hood or some other sort of exhaust fan at your
workstation?

Bugger me - I'm glad you lot are not troubleshooting a nuclear power station!
The Weller WTCP must be one of the simplest decent temperature controlled irons on the market, mine runs 15hrs/day and does so year in / year out. Sometimes more when I forget to turn it off - the new ones dont have the neon in the mains switch so it does happen - I have 2 of them now, one on each bench...

Test procedure.

1. Runs continually, therefore base station and element OK.

2. Check switch - unscrew bit retainer and remove (iron off). Pull tip in and out - should hear click if switch working. If not, then switch or tip faulty.

3. LOOK at tip, see if mangnet thingo at bottom has fallen of - if so, buy new tip (and after all the years youve had it, I wonder if it could solder anything except 2 wires together, my tips last about 3 months on average, I buy them by the half dozen). If tip defective, completely dismantle iron and remove magnet from switch assembly.

4. If tip OK (go on, be a devil, buy a new one anyway....) then switch faulty. Buy new one.

5. Exception to item 4 - if you have done bugger all maintenance to your iron, clean the garbage out of the barrel - it is rare for switches to fail "on" (never had one do it, as a matter of fact, but have only been using Wellers for 20 years so it COULD happen...) - use a bamboo satay skewer to clean out the crap, then follow procedure 2.

Hope this helps,

de VK3BFA Andrew (at 50, an "official old grump")

Thanks so much everyone. I was really surprised by the quick and
informational responses.
Everything was in great detail... even detailed enough for me to figure it
out. I'll give it a try and let you know how it worked.

I just got licensed Monday and I've been dying to get on the air. Thanks for
your help.

Regards,
KC9FFX

I have heard this from some other user - but I have tips that last years -
BUT I
only use the 700 degree tips.

> 4. If tip OK (go on, be a devil, buy a new one anyway....) then switch
> faulty. Buy new one.

A spare tip should always be available on the bench. I just repaired an
older WTCPN station
an the college student had placed an "ET" tip (aka tips are all the same
right! - wrong)
from the Weller EC1000/EC2000/WES50/WES51 models.
Glowed cherry red -- changing to the proper tip -- corrected problem.

> 5. Exception to item 4 - if you have done bugger all maintenance to

I saw my first internally shorted SW60 last year (although I think the user
had wacked it against a hard surface to
cause this type of damage). I also have seen a "kinked" spring -- near as I
can tell -- originally assembled that way --
over a decade earlier. I never saw a heater fail as shorted (dead short -
but not heating) until last year -- all previous ones
failed as "open". See enough stations and you see many failures, bad
operating practices and unique equipment abuse.

Who comes up with these things - now we have to go to a new solder
formulation not as good as the old one - a bit like FREON - dont worry
about the millions of Asian countries using FREON in the
refridgerators, get the can out of the workshop and the world will be
a better place. (the fact that the patents have expired on FREON but
not the replacements is pure co-incidence, I'm sure...)

I have been using lead based solder for 30 years - no precautions. For 20 years I was a cable jointer with Telecom wiping lead sleeves onto cable, using bar solder and a propane torch at the bottom of a ill ventilated manhole -the only precaution I took was not to use the same pocket knife I scraped lead with to cut my lunch - somtimes I did, but I ALWAYS wiped the blade on the grass before I did. 20 years of blood testing revealed NO higher levels of lead than general environmental exposure.

Andrew VK3BFA

PS - does your XYL believe in the healing power of crystals as well?

I haven't. But you must be very careful. Read the following quote from
a paper on non-lead solders. Although directed at one combination, it
illustrates the problems inherent with mixing differing solder types.

I want it for the same reason I want manuals for all of my equipment.
It saves a lot of time locating part numbers when you do a repair. I
have used, and repaired, these soldering stations off and on for years,
but I always had to wait for the distributor to look up the part
numbers.

BTW, I don't do nuclear power, but I did build and test telemetry equipment used by NASA, including a KU band receiving system aboard the International Space Station.

The Weller stations were banned from the production line because of a surge in leakage current when the thermostat tripped in the heating element, and we were required to use irons with grounded tips that could reliably measure under three ohms from the hot tip to the electrical ground on the bench. They were replaced with Ungar "Loner" irons with electronic temperature control.

I used a spare DMM connected between ground and a piece of scrap copper to quickly test the resistance any time any of the three irons had sat idle. I used the irons so many hours a day they tips only lasted a few weeks before the iron plating was pitted, and would no longer go below three ohms. I threw out a lot of tips that could have been used in non ESD situations, but we couldn't risk someone reusing a bad tip, so they went into the recycling bin with other solder related scrap.

I have five dead Weller soldering stations I picked up that will need new irons, after someone tried to "Fix" them, and left the irons in pieces.

OK - As long as we have all this Weller knowledge here, who has the secret stash of tips for the W200 iron? Yes, they made a 200 watt iron with the magnetic temperature control, but I have been unable to find parts for many years. Can't find W200 on the Weller web site.

Thanks in advance.

If you must replace a defective 40673 in an existing design this is a good deal. However, these parts are dated and not that great by modern standards. You can buy much better (though only in SMT) parts which are still in production--such as the BF998--for a few cents each.

So, for replacement, yes, but why anyone would use them in a new design or an adaptation of an old design is a mystery...but of course, tubes still seem to attract some folks, too...

That's is one of the reasons why a 9 volt battery is probably the
highest potential you will seen in my kits. The manuals I write are
full of precautions about soldering, erecting antennas, etc....but NO
high voltages...

But I still remember the jolt I got as a kid which caused me to drop a
heavy chassis on my toe...How did WE survive?

==========

But perhaps the most important effect of this method of creating a
multi-band or wideband tuned circuit is big deterioration in effective
operating Q.

Once upon a time it was a popular PA tuned-tank, minimum-dip, arrangement.
At the higher frequencies the coils got hot. Too high a circulating current
in the tank. Poor efficiency. They didn't catch on!

Varactor diodes used in receiver and local oscillator circuits have a
relatively poor Q to begin with. Perhaps lower than coil Q. Series tuned
circuits in parallel with shunt tuned circuits only magnify adverse varactor
effects.

Seriously, you'd better consider the effects of the fumes from the solder
fluxes. Since our shop is in an office environment, I bought some devices
from TechniTool to solve the problem of solder fumes. At first glance
they resemble a small bench lamps, but house a small fan and charcoal
filter.
The moveable arm allows them to placed near the work area where the
soldering is done.

OK here is what is going on as far as I know now.

The 3.5 MHz transmitter is to study sea wave propagation at that frequency over saltwater at a defined altitude. I am not 100% certain what that means but I will ask for more detail.

As to legality I will ask the person that I am getting the information for what they have done in the way of research on this part. This group is normally very good on researching these matters. It might be that they will actually have the transmitter commanded from a UHF control link. I just don't know for certain.

I will also pass on the information about the organizations that are doing the balloon launches. It is always helpful to learn from other people.

Thanks for all the information so far folks. If there is anymore avaialble please post it here to the news group so that we can all learn from each other.

Hi Simon
I have the tx section working great, a local station can hear my carrier
very strong, but the modulation is very distorted. I am using an electret
microphone, I may try a different mic. I will keep you posted if you send
your email. Please let me know if you encounter the same problems.
Hope to hear from you soon.
I would be very greatful if anyone has any ideas on how to test the mic amp
circuit.

Hi. Anybody developed a nbfm RX project covering the FM band (appx 87.5Mhz-108Mhx).

With digital readout, though I suppose I could just hook up a simple a frequency counter to read frequency.

TIA. Rich.

I'll take a look and see. The station came with two tips, both #7, but in
the 11-odd years I've owned the iron I've never used the second one.

>highest Q in a given volume, go for a coil with roughly equal length
>and diameter, though that's not terribly critical.

No need for a computer program for using data in the July 1977 issue of Ham Radio magazine article "Self-Supporting Coils."

While inductance over 0.50 uHy is not on the chart of Figure 1, the 0.55 uHy value will be very close for 9 turns of #12 bare copper (standard electrical wire with insulation stripped off) wound on a paint roller ferrule's threaded end of a paint roller pole. That's the same threading for all sorts of portable appliance items for the home; about 5/8" inside diameter, 1 turn per 3/16" length. Q at 30 MHz will exceed 300.

Well before that article got into print I sat down with a calibrated Boonton 190A Q Meter and got wound up on forms from 4-40 screw to a standard 117 VAC light bulb base. By using the largest solid wire that fits the threading, the coil will be quite self-supporting without any core material. The screw thread can be unscrewed easily and the finished coil diameter will increase slightly in so doing. Form leads as desired with long-nose pliers; long leads will also add some inductance. Measurement of inductance and Q was done on a simple solder-it-in-place fixture on the 190A.

I can e-mail repro scans of the article to anyone interested (1.2 MB).
As the author I have the right to do that under "First Rights only"
compensation. :-)

NBFM? As in narrow band?

What would be the point? Here in the U.S. at least, that entire
band is assigned to FM broadcasting, and it is anything but narrow-band.
Typical deviation from a broadcast station is 75+ kHz.

Maybe I used the wrong term. I think lots of HiFi tuners have very wide filters much greater than 75 Khz. For DXing it seems then you need no more than say 75Khz. A tuner with that bandwidth would, in a sense, (Ithink) compared to a regular HiFi tuneer be a narrow bandwidth tuner.

BTW, what would be the result if you used say a 20Khz filter on a FM signal with 75 Khz deviation? Would you get distortion or a perfectly copyable signal. I mean is it the analagous to using a 2Khz filter for an AM signal transmitted at 6Khz wide?

It wouldn't be quite the same. You would be clipping the sidebands, and experience quite a bit of distortion. A 110kHz filter is about as narrow as you can go.
I've been meaning to come up with a tuner that would be in the class of a McIntosh MR78 for the past couple of years, but something has always come up. Maybe after my current project, I will do this, if there is enough interest.

Well then you're stuck with 80 meters. But I'd guess 5W output would
be plenty for your purposes. However, I'd be very interested in the
type of antenna you eventually settle on for this unusual purpose.
Nothing really springs to mind as being particularly suitable...

I have picked up a number of NOS Weller items (no longer in production) this
past year (from a number of sources) --
due to the relocation of the Weller production facilities in the Carolinas
to Mexico.

You can call Weller (North Carolina) and ask for Mr. Larry Smith (who is
Weller's product line manager and engineering support)
IF Weller is no longer making the part, Mr. Smith or "Dino" who leads the
repair center -- was know of a source !

David,

Glad to hear you have the RF section working well, as far as the modulator goes I would treat it as a stand-alone mic amplifier circuit. I would suggest you connect the output pin 5 of the LM386 to a speaker via a 220uF electrolytic cap (+ towards the pin 5) and monitor the modulation quality from the speaker.

73's Simon G7CPN.

I hear that FM RX's are pretty complicated affairs. Most FM DXers it seems
just modify commercial sets. Reduce bandwidth from say 230Khz to 110 Khz. I
suppose that going this way has quite a lot of merit. Cheaper probably.

You need to refresh your personal databanks on basic modulation.

In FM the modulation amplitude "swings the frequency up and down
in frequency." [close and simplistic, there's a bit more to it...]
Limiting the bandwidth of the receiver is the same as clipping the
peaks of an amplitude modulation. You WILL get a LOT of
distortion on high-amplitude modulation input at a station.

In a limited-bandwidth AM receiver there is no limit on the amplitude
of an AM signal, just the frequency range of the modulation signal.

In a limited-bandwidth FM receiver there is both a limit on the
amplitude and frequency range of the modulation signal.

Hi

I've got some nice MCL UNCL-R1H-2 mixers from Mini-Circuits that I
finally have a use for.
MCL's current catalog lists the UNCL-R1 specs and a google shows the
general specs of the UNCL-R1H variant (17 dbm LO instead of 7dbm) but I
can't find anything on the -2 variant (UNCL-R1H-2.

If you have an old MCL catalog could you look it up for me and let me
know what the difference is (or send a list of the relevant specs).

TIA & 73,
Lenny W2BVH

For most people, it makes more sense to simply change the filters
in an existing FM BCB receiver than start from scratch. Indeed,
it seems to be a relatively common practice among people who DX
that band.

Not that building something from scratch wouldn't be interesing,
only that if "narrow bandwidth" is all that's wanted, then there's
no sense in building it all. And there isn't much sense in putting
narrow filters in a mediocre homebuilt FM receiver, which is the
sort of thing you see in construction articles.

I use Delco digitally tuned car radios as my "table radios", running
them off power supplies. For the price, a few dollars at garage sales,
they are pretty good receivers on the FM band. I know it would benefit
from a narrow filter for a few stations I like to listen to. But of course,
a lot of FM receivers aren't that great for distant reception, being too
sensitive, without good overload protection.

In some cases, it might be intriguing to build a single channel FM
BCB receiver. Build it like a ham band converter, with plenty of
tuned circuits at the fronte end, little or no RF amplification,
and a good mixer. Being fixed tuned, one could optimize it for
that frequency, and not worry about tracking, or the problems of
ganging a number of tuned circuits. For the local oscillator, one
could go with a crystal oscillator chain.

It's certainly the most bang for the buck. Really, a good FM receiver isn't much more complicated than a good AM receiver -- but a bare-bones-just-barely-receives-the-strongest-stations FM receiver is quite a bit more complicated than a bare-bones-..... AM set.

Usually you can reduce the bandwidth of a FM receiver by simply removing the monolithic ceramic filters and replacing them. I've done that on my Technics ST-G50; at my location 30 miles outside Nashville, I have received at least one DX station on every frequency that doesn't have a local. (yes, that includes the frequencies adjacent to 100,000-watt locals)

Forget what I paid for the filters - it was definitely less than $5 apiece. My tuner needed two.

==========

Regarding going to 20KHz bandwidth...

In DX situations with heavy interference, a very narrow bandwidth might be helpful for identifying DX stations. The programming will be mostly unintelligible in a 20KHz bandwidth, but maybe it'll be more intelligible than it would be against the interference from adjacent channels in a more reasonable bandwidth.

I occasionally use the narrow filters in my TH-F6 HT to DX television audio. Nobody would dream of listening to that audio for entertainment but one can identify things they'd never ID on a TV set.

Don't know anyone who's tried putting a 10.7MHz IF 20KHz or similar bandwidth filter in a FM broadcast tuner. You'd want it to be one of multiple bandwidths, so you could select something more reasonable for stronger signals.

Yes, you used the wrong term<grin>.

"NBFM" has a specific technical meaning, IIRC a system where the
modulation index (ratio of peak deviation to maximum modulating
frequency) is less than 1.

For FM broadcast, the peak deviation is 75KHz and the maximum modulating
frequency 15KHz. (OK, I'm ignoring stereo...) So the modulation index
is 5.

For police radio, the peak deviation is roughly 3KHz and so is the
maximum modulating frequency. So the modulation index is 1.

> BTW, what would be the result if you used say a 20Khz filter on a FM signal
> with 75 Khz deviation? Would you get distortion or a perfectly copyable
> signal. I mean is it the analagous to using a 2Khz filter for an AM signal
> transmitted at 6Khz wide?

Lots of distortion.

In AM, distance from the center of the channel correlates to modulating
frequency. Restricting the filter bandwidth in the receiver restricts
the frequency response - the high audio frequencies ("treble") are
rolled off. But it has no effect on the range of *amplitudes* that can
be received; a loud sound within the bandpass of the filter will still
be reproduced accurately.

In FM, distance from the center of the channel correlates to modulating
amplitude. A loud sound will push the transmitted signal to the outer
edges of the channel. If the receiver's filter is too narrow to pass
that, the signal peaks will be chopped off, resulting in severe
interference.

Remember that the 75KHz peak deviation for FM broadcast is 75KHz *either
side* of center. To get the actual bandwidth required you have to add
the peak modulating frequency to that. 165KHz, not counting stereo.

You can chop some of that off at the expense of some distortion. I've
found in practice, 110KHz filters work fine for DXing though I wouldn't
want to listen to a symphony through them. 75KHz would probably be
reasonably intelligible.

If you want to do DX'ing get an existing receiver and put in a
narrower filter. Many of the older tuners are ideal for this. I saw
writeups on this in magazines over 20 years ago and don't remember
what bandwidth filter was recommended.

An interesting project would be mods to the GE SuperRadio II or III.
They are cheap, available and have a tuned RF stage.

G3RZP mention the use of 6J7 as detector in his HRO, see Radcom nr
1/2004 page 45. It is described as combined AM/SSB detector, but I
wonder what sort of detector it is for AM. Is it grid or anode
detector? It is shown on http://home.online.no/~la8ak/17r.htm
Suppose it is still low level IF for AM - as for SSB.

On http://home.online.no/~la8ak/17s.htm I've shown the application of
a triode-hexode ACH1 which may be somewhat similar to 6K8, but here
the control grid is biassed with -4V and obviously operates as a
completely different AM-detector.

That's a bit misleading. Most FM BCB receivers, now and in the past,
have an RF stage ahead of the mixer, and it is tuned. I once had
a nice Sony stereo receiver that worked well on FM, and it's lack of
an amplifer ahead of the mixer was pretty uncommon (and likely accounted
for it's good overload resistance).

The "TRF" stage in a Superradio is in reference to the AM band,
where in non-car radios, an RF stage is an exception.

Also, while it does seem a bit of work has been done in the design
for better AM reception, that RF stage and the better than average
loopstick, it does not seem like the FM section is anything to write
home about. I gather it's a fairly generic design.

This is part of the mythology of the Superradio. It's not all that
great, just maybe a little bit better than the average portable or
table radio, but people point to it when the concept of "a better
radio" comes up. Once you start spending the money, better to spend it
on a better design. Or better, buy a car radio that will have good
reception, or some used stereo that did have a bit of extra care in it's
design, so it actually won't overload in an urban environment.

usually when mini circuits puts a dash number on their parts it is to
indicate a different frequency range for that part. The H variant indicates
a different signal level as you noticed. In the case of other mixer
parts the
-2 variant was a higher frequency part.

And an essentially uncalibrated frequency dial. Pretty bad for DXing IMO.

Almost any digitally-tuned car radio would be better for DXing. Remember
that cars drive through all the worst reception areas and their radios have
to at least try to work there.

Going to www.KitsAndParts.com by Dieter Gentzow, W8DIZ,
you can find the old Motorola MC3362P (2 for $4) which is a
complete FM receiver IC. There's a full Motorola datasheet there
with application data. A one-IC FM receiver for headphones.

For some audio power output, he has National LM380s at 4 for $5.
For an RF preamp, he has Fairchild J310 J-FETs at 12 for $4.
There's also a respectable number of Micrometals toroid cores for
IF and RF filtering. Datasheets for all except a full info range on
the Micrometals cores (which some think are made by Amidon).
www.micrometals.com for full core information.

If the MC3362 is too much or too little, Dieter has 612 Gilbert cell
ICs for mixer-oscillator applications and MC1349 gain blocks (its a
slightly higher gain version of MC1350) for the IF.

A fairly good supplier of oldies but goodies in semiconductors and
toroid cores.

Actually, they aren't much different than an AM design, except that
generally, you use quadrature detection for demodulation, and that you have
a deemphasis filter. The I.F. bandwidth is different, but pretty much
everything else is the same.

I was thinking about going with a high level mixer, something with an IP3 in the +30dBm range. I would probably make it a double conversion unit. This way, I could use a bandpass filter at the front end.
You are right, though.....there are quite a few good performers already on the market, and those auto radios are no exception. The newer ones that use the Philips dual conversion chipset are very good on the AM broadcast band, too.

4468. Re: Avantec MMIC

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-21 09:07:58 UTC
From: Pete KE9OA <n.gianakopoulos@worldnet.att.net>
Message-ID: <OpdFb.504424$0v4.21746832@bgtnsc04-news.ops.worldnet.att.net>
Source record: 30085

This is a 10 to 400MHz thin film cascadable amplifier. Typical operating
point is 5V@15mA. Output power is +8.7dBm@1dB compression, with a NF of 4dB.
Looking from the bottom view, if you set the tab at the 5:00 position, the
pinout is like this:
3:00 pin is RF out, 6:00 is V+, 9:00 is RF in, while 12:00 is Ground.
I hope this helps.

Many times, they also do that when they make a special part for a customer.
When I was at Rockwell, we had some MCL parts that were identical to the off
the shelf part, except that they were screened for closer tolerances.

Were you involved with either the SVR-4F or 55U3-1SC C-band
commercial Satellite receivers? A CATV company I worked for had piles of
the SVR-4F receivers that I repaired at our Cincinnati Ohio system. They
were shipped to me from all over the US because of the long turnaround
time for factory service. I still have a few parts from units that were
too expensive to fix. I have 10 Microwave Associates 3.4 to 4.2 GHz
isolators (7K75Z) sitting in front of me from the five units I scrapped.
I think I still have a number of modules for the 55U3-1SC in a box out
in my shop.

I'd like to have seen the photo of tube sockets hanging by the wiring!
Or did he completely 're-kit' the rig and rebuild?
Either way a nice job. I thought Drake was the only company that
used copper plated chassis (or was the C line built on solid copper
chassis?)

There was an article in QST (or maybe CQ) within the past few years
by someone who had rebuilt a kit. He had stripped it down. Then he
cleaned off the chassis, and sent it out to be plated. And then he built
it up. I can't remember what he said about the parts he used, if he
used pretty much what was there, or replaced all but the unique parts.

Perhaps this latest article is by the same guy.

The reason for banning lead solder isn't that it is dangerous to people
using it,
but rather that old electronic equipment ends up in landfill and so does
the lead.
Auto batteries require special disposal for this reason. The idea is to
ban the use
of lead in all products (where possible) to eliminate disposal problems.

But just how good IS lead free solder? I guess it DOES work well in
plumbing
where it has been in use for many years.

If lead is insoluble in water, then WHY isn't it used in plumbing? The
small
amount that it IS soluble is the danger. Guess the Romans went mad due
to their
use of lead pipes (that's where the word plumber comes from, the latin
for lead
is plumbum, and the atomic symbol for lead is Pb). Could be the lead
pipes were
the reason for the fall of the empire?

Lead is NEARLY insoluble in water, but the more acid the water is, the more soluble it becomes.

And to answer your question, it WAS used in plumbing for many years until someone made the connection. Just like carbon tetrachloride for dry cleaning or asbestos for insulation.

Like I said the word 'plumber' comes from the latin plumbum meaning
lead. Ancient Rome was the first to use lead pipes. Could be why
Nero was mad as a hatter.

4483. Weller TC-201P & later irons

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-21 22:24:27 UTC
From: "G.Beat" <now9spamgb@spam.comcast.net>
Message-ID: <v4pFb.108311$8y1.330970@attbi_s52>
Source record: 30000

Comments Apply to the Weller WTCP series of soldering stations:

Weller / Cooper Tools changed the style and construction of the North American version of the TCP irons during the 1980's (From the original TCP-1 and TC-201 irons to the new TC-201P). This change corresponded to design changes to other Weller stations and products (specifically the "EC" series).

The most significant design change was the replacement of the "wired-in" heater (TC-208) used in the TCP-1 and TC-201 irons with a new plug-in heater (EC-234) first introduced with the TC-201P iron.

The replacement of a failed heater - was made simpler and allowed for a standardization of this heater with the heater used with the company's EC1201A soldering iron.

Unfortunately, if a user or technician needs to replace the SW60 magnistat switch or the line cord - the socket contacts (AMP Audio/Microphone connector socket contact) needs to be removed from the new black plastic insulator.

The specific AMP Extraction tool for this procedure is part number 91136-1. A "bobby pin" is suggested as an alternative in Weller's SW60 Magnistat switch instructions.

Greg
w9gb

BTW, regarding an earlier comment on repairing Weller WTCP series iron -- these AMP connectors were first made at AMP's Harrisburg, PA facility. That is about as close to a nuclear plant as this procedure will get.

Actually Collins radio used the original TCP stations (black bakelite) on
their productions lines and for repair in the 1950s and 1960s
(5 of these from Collins surplus were the first ones that I repaired in
1975 - as I started college)

The original ones did not have the switch OR neon bulb ... and they ran 24
hours/day at Collins.

Darn shame, but components have changed as well as their tolerance to ESD.

> I have five dead Weller soldering stations I picked up that will need
> new irons, after someone tried to "Fix" them, and left the irons in
> pieces.

I assume the later WTCPS and WTCPT models? In addition to the ESD
requirement, "T" model changed the 3 amp fuse
on the transformer's secondary (to protect transformer from a heater short)
to a 6/10 amp fuse on the transformer primary
(and an MOV across primary on some models).

I don't know which model they were using. They were pulled from the
production floor a year before I was hired. They were in storage in a

separate building, and I was never able to get my hands on them They were probably destroyed last year when the plant was closed and moved to Pennsylvania. I kept hearing the old timers complain about the new irons because they had used the Wellers for years, and didn't like to do the extra maintenance on their "Loner" irons.

Well, no, not so far as I've found. But they _did_ use lead water
piping, and they _did_ use lead acetate ("sugar of lead") as a
condiment.

The first is bad only where the water's mildly acidic.

The _second_ is Just Plain Bad.

A guess would be that plumbing was a luxury, for a few in the upper
class. The rest of us had to carry water from the well, avoiding
lead pipes.

They were poisoning themselves with lead, but it wasn't from the
plumbing. The water that was carried to Rome from the aqueducts was
extremely hard, and a layer of calcium formed on the interior of the
pipes just about immediately after being put in use.

Where they got their lead was from storage containers for wine. They used lead containers for this! I believe they credited the lead with preservative powers. The acidic wine pulled a lot of lead out ot the container and into the gullets of the drinkers.

Is this for the female pins in the base? THose pins are the only
consistent source of trouble that I've ever had in over 25 years of
using the WTCP? series of Weller irons. Weller went thru several
generations of WTCP irons where some of those pins were crimped onto
tinned magnet wire. The crimps generally lose good contact within a
year and generate heat in the socket, which melts the connector body.

I LOVE these solder stations, but the very first thing I always do is
take those pins out and solder them.

I think I'll order one of the AMP extractors. I've always had a hard
time getting these apart gracefully. Thanks for the info.

4497. Pixie 2 freq change question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-22 05:32:25 UTC
From: jim&julz <shrumj@spamsucks.madisontelco.com>
Message-ID: <bs5v8a$2s27$1@news3.infoave.net>
Source record: 30014

Greetings,
I have been planning to mod my pixie 2 as to switch between multiple xtals/inductors for changing between 80/40/20 etc...

I was going to use a rotary switch to change to the different inductor and xtal, depending on the selected band. However, I realize that the inductors will be about 2 inches from the main board since it will be wired into the rotary switch. Will this additional wiring greatly change my inductance? I assumed that it would, but I wanted some more experienced opinions.

Thanks...

I have built several of the Ramsey and sorry to say that the other
guys were right. I never was satisfied with any of their performance.
I also have built a couple of the Ten Tec kits and found them to far
superior to the ramsey units.

Just my 2 cents.

Jim -

Yes, I was referring to the "Socket" connectors (AMP Part number: 207437-2
or 207437-3)
in the black plastic insulator [the pins (3) are on the Weller EC234 plug-in
heater assembly]

Here are the specific AMP document ID's / web page reference.

Audio/Microphone Connectors - Specification Or Standard (Application
Specification): 114-10011

AMP* EXTRACTION TOOL 91136-1 Specification Or Standard (Instruction Sheet
(U.S.): 408-7859

Catalog Page AUDIO/INSTRUMENT CONNECTORS: 82053_0794_2

http://ecommas.tycoelectronics.com/commerce/DocumentDelivery/DDEController

The tool is available from DigiKey and Mouser (I do not remember which one had the AMP tool in stock) -
BUT it is NOT cheap (as I remember - over $ 25)

BTW, TYCO Electronics may have changed this original AMP part number - since it took both Mouser and DigiKey a bit of time to cross reference the part number.

Even if you used lead free solder, you would not be lead free. After all, your component leads and your printed circuit boards use tin/lead solder to insure solderability. Until all of the components are lead free, you will be chasing smoke. this is especially true when repairing old electronics.

If you use a non-lead solder with leaded components, you will most likely creat brittle intermetallics which will greatly reduce the reliability of your equipment. The biggest problem to date is the intermixing of various solder compostions. Uncontrolled mixtures with unknown proberties are created.

Yes, I know, there are lead free leaded components. For example, gold plated leads on ICs. But, these do create brittle intermetallics if the solering process is not exact. And I doubt it is exact when using a soldering iron.

A few years ago, I worked in a lab where we evaluated various solders for our customers. Things may have changed since then, but believe me, you don't want to do it yet.

Al

<< I was going to use a rotary switch to change to the different inductor and xtal, depending on the selected band. However, I realize that the inductors will be about 2 inches from the main board since it will be wired into the rotary switch >>

James-

At these frequencies the difference in inductance will probably require a slightly different capacitor setting, but that shouldn't be a problem.

I would be more concerned about coupling of energy from the coils back into a circuit at an earlier stage, such as to the crystals. This might result in an unexpected oscillation at some frequency other than intended, in addition to the intended frequency. If that occurred, there would be mixing of the two frequencies, generating sums and differences of the fundamentals and their harmonics.

You might consider two separate switches for inductors and crystals, keeping them separated as much as possible. Otherwise, look for a multiple-wafer switch with a LONG shaft to separate the wafers.

73, Fred, K4DII
(My amplifiers oscillate, but my oscillators don't!)

Considering the above , I shall stock up with solder currently available eg
with lead.
Even when it is stated (in another message earlier in this thread) that only
'fresh' rosin core solder will give the best results.

4506. FS: Sierra 121 Tunable VTVM/VLF Rcvr

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-22 16:59:32 UTC
From: Walter Treftz <pendragon@netsignia.net>
Message-ID: <3FE722DF.1816ED15@netsignia.net>
Source record: 30022

FS: Sierra 121-A, tunable VTVM

Freq range: 10khz - 510 khz

Controls:
Attn Steps: -60/.001, -50/.003, -40/.01, -30/.03, -20/.1, -10/.3,
and 0/1
Input Level: 0/1, +10/3, +20/10, +30/30, +40/100
Injector Sw: CAL & REC
Meter Sw: CAL & REC
IF & AF gains
Headphone jack on front panel
Meter Scales: -10 to +2 db, 0-1v & 0-3v

Comes with manual copy and my parts replacement notes.

I got this at a hamfest with intent of using for VLF rcvr. Bought
a manual and started replacing parts (leaky caps, out-of-
tolerance resistors, etc) even though it was working (having
never used one, had no idea if it was working well or not but
signal generator punches through). THEN, couple weeks ago picked
up a Sierra 128-A (same gadget) at another 'fest and it appears
this is the one to keep (rack-mount like rest of my station,
solid-state, much larger freq range - DC to about 15 mhz, etc.)

Can send digital pix if desired.

If interested, make a reasonable offer. Buyer pays shipping.
No extra charge to pack up and haul to USPO or UPS. If in central
Florida, can deliver (Gainesville to St.Pete)
for gas or beer.

Any questions, contact direct at --
--- pendragon@netsignia.net
--- hvalver/at/hotmail/dot/com
--- rosemarytreftz/at/yahoo/dot/com

or (352) 637-1755

73 Walt (N4GL)

BTW, if anyone reading this has a 128-A and the manual, would
like to hear from them re getting a copy.

While you're at it, check one more thing! If the problem turns out to be welded contacts on the thermostat switch, check that the MOV across the secondary of the transformer is still good. I had one that repeatedly welded the contacts till I replaced the MOV and has worked for 5 years now without a problem.

I would agree.

Just like with house painting, using oil-based over oil-based paint,
and latex over latex paint, you really don't want to mix.

Although the metallurgy of mixing different solders could be
fascinating, the performance might not be, especially in harsh
environments (temp cycles or physical roughness).

There are no rectifiers in the WTCP series base ... all AC. Weller does
make a heater for this series that
works at 12 volts (DC) for mobile work.

The MOV (Metal Oxide Varistor) is a surge supressor whose only function
is to absorb the "kick" when the mechanical thermostat opens (or
"bounces" when closing). The one in the Weller unit (if memory serves)
clamps the voltage at about 40 volts (Transformer secondary is 24 VAC).
If it isn't working properly the thermostat contacts arc and weld shut,
causing runaway overheating.

Easy there Mr Squire!
>
> Come on! Isn't there anyone out there actually useing lead free solder in
> thier circuits?

There probably aren't a whole lot. If you looked at the Kester Pages,
you can see that the other solders are at best a compromise. Lead isn't
used in solder because of some coonspiracy among Troglodyte hams, ist is
used because it works bery well. Most other solders either need a large
amount of heat, don't flow well, have poor wetting, or are brittle.

http://www.efunda.com/materials/solders/types.cfm

has a nice comparison between types

http://www.aimsolder.com/techarticles/Antimony%20Study.pdf

is a nice pdf regarding Antimony containig solder

Here is a page of links that has some interestinf info:

http://www.aimsolder.com/lead_free.cfm?section=articles

Especially the:

Materials and Process Considerations for Lead-Free Electronics Assembly

BOttoom line is that using tin lead solders is not particularly
dangerous from a user perspective, that it is a problem in landfills,
and that there are interesting considerations if you want to use other
types of solder.

Might as well learn all ya can!

I'm in no hurry to dump tin lead, but I'm curious why tin/antimony isn't used more, unless it is because of the likelyhood of comeing into contact with lead.

This isn't a direct solution but it looked interesting if someone wants
to try it - Harry Lythall's accidental discovery of an LM317 series
voltage regulator as an RF oscillator at low HF.

http://w1.859.telia.com/~u85920178/tx/317-tx.htm

Use a toroidal core and/or a multiplying rectifier and the voltage could
be sizeable.

Hello,
I'm looking to rig up a cheap way
to monitor the local repeater without having to invest in a complete
transceiver.

I've just gotten into VHF ham radio (HF is more familiar to me). I'm not too
strong in making radio receivers, but I made VCO's, so I have some homebrew
skills:-)
I need a 2m receiver circuit, with good selectivity and stable frequency.
I've seen some easy to build circuits with good performance on Motorola
IC's, but I can't find that circuit in my country. Well in my country there
is a bit difficult to buy any kit or specific parts, so I will do everything
from parts I could find at local radio shack store.

Any suggestions/help would be greatly appreciated.

Thanks,
Edgar

==========
Harvey , Tnx for the useful info . I was interested in the spike voltage
suppression level of the MOV, which is required since the heater element is
for AC . In the event of DC a reversely connected diode would have done the
trick .

BUY something?? Sort of misses the point of posting to
rec.radio.ameteur.HOMEBREW, doesn't it? Anyway, none of us have any money!
;-)

For my money, I would probably follow a design of a crystal controlled RX
(one channel with probably the same drift as the TX you want to hear!).
There are several designs for this, but consider a few small things first:

1. How local is local? Is the repeater within ~10km - and is there
another powerful signal on a close frequency)? If there is a powerful
local signal, you might have to select your design to be more selective.

2. What aerial can you have? Again, if the repeater is strong and the
other close signals are weak, you can use a very simple radio and still get
good results.

3. How much radio building and fault-finding experience you have.

Look at the chips in the Philips SA604AD/SA605AD line. They're great
for FM receiver construction.

Source record: 30046

There have been ex-MOD radiosondes for sale on Ebay UK for a while now and there seems to have been no shortage of buyers (and least one person who seems to bid on them all). Some of them include a GPS receiver, though not a fully featured one - it reports only how much it's moved rather than where it is. The GPS versions fetch a higher price than the ones without so presumably there's something you can actually use these modules for. Does anyone know what?

Perhaps I should buy one rather than risk being the only Radio Amateur in my street without my own radiosonde....

These units are probably useful if you are interested in equipping yourself
with a (mobile) APRS or UI-View system.
However ,beware! Ensure that you get hold of info (if not included with the
hardware) how to interface them.
Also beware of 'e-bay fever'. Goods sold on e-bay often fetch higher
prices than identical equipment sold through the official trade channels.

Trying to replace a burnt out transistor that I think was a regulator, was attached to a heat sink so it was involved in power or amplification I guess, anyway its located in a power supply and has the code k1821 on it and a logo saying FC as well...and thats all. I cant find any info on this thing, anyhelp is appreciated!!

4533. Introducing Rapi-Morse

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-24 22:49:52 UTC
From: Biz WD=?ISO-8859-1?B?2A==?=HCO <wd0hco@ev1.net>
Message-ID: <BC0F7430.A6C4%wd0hco@ev1.net>
Source record: 29900

WDï¿½HCO's Rapi-MORSE

The World's first interactive Morse code table.

With Rapi-MORSE, anyone can decode Morse code messages by ear within 20 to 30 seconds after starting the program. You don't need to know the Morse code.

That's Right! It's not a TYPO! 20 to 30 SECONDS after starting this program!

You can also use this program with you favorite Morse code teaching program to quickly learn the Morse code and quickly pass that FCC Ham Morse code test. Many students report 50% to 75% improvements in code character retention than just memorizing the code using a Morse tutoring program alone.

How does Rapi-Morse work?

Simple, by doing what scientific research show us the human brain is good at.

Manipulating Objects and embedding them within a Geographic Space.

Furthermore, the use of Internationally recognized standard Traffic Light colors... RED YELLOW GREEN will quickly and easily differentiate between DOTS and DASHES.

But the best part is that this program is FREE and gladly given to anyone with an interest in learning or using the Morse Code.

It comes in two versions:

This one for all Windows Computers:
Rapi-MORSE.exe

This version for all Mac Computers:
Rapi-MORSE

Rapi-MORSE is freeware and was invented and written by Biz Wichy WDï¿½HCO

Get it at:

http://users.ev1.net/~wd0hco/

Hi,

It may be a 2SK821 FET. Do a Google search for the NTE web site and
crossreference it.

Let me make a suggestion as to improving this circuit. IIRC he used the
high gain triode of the 6af11 as the detector, instead use the other triode
(low gain) as the detector. Then wire the first af stage as a combined
grounded
grid rf amp and grounded cathode af amp. This is known as a reflex amp.
to do this use an rf choke in the cathode, plate, and grid. Ground the grid
with a 470 pf cap, feed the af from the detector to the grid through a 1mh
rf choke. Use a 2.5 mh choke in the plate, taking the af out through
the choke
and couple the plate of the tube to the detector via a 10pf cap. A
500uh choke
in the cathode and then the normal bias resitor bypassed for af.
Connect the
antenna via a .001 cap to the cathode. Different value chokes are used
to prevent
turning the amplifier stage into an oscillator if two of the chokes were
resonant

at the same frequency. The plug in coil now only needs two windings.
Use a 47k - 100k resistor as the plate load for the detector and a
200pf variable
throttle cap as the regen control instead of the pot. Use a 100k
resistor as the
plate load for the af stage. See the Aug 1966 issue of PE for a similar
radio
using two tubes (12at7 and 6ak6).

If the soldered components are of the 0.1 or 0.15 inch pitched type I would suggest you apply a solder (spring operated piston) sucker instead of desoldering braid . Reason : less heat is applied to the components if these are to be re-used. The same applies to the PCB especially if it is a repair job ,hence the PCB is to be retained .Personally I have not been very successful with desoldering braid , but that is perhaps due to a lack of skill . With a sucker I have never had any problems , desoldering components on the above type of boards.

Whatever brand of wicking solder braid you use, fresher is much
better. Once the surface oxidizes, it will be far more difficult to
get good results.

I use copper braid dipped in liquid rosin flux (RMA). One tip is to live about 1/16" of braid with the solder in it when you clip it off. Then put that part against the joint before applying heat. It can will conduct heat to the old joint faster, and do less damage. The method is called "Wet wicking" Keep in mind that wave soldered boards were done with 80/20 solder so it would cool before leads had a chance to move. So, you may need to clean the surface of the old solder before removing it. Apply a thin bead of RMA flux along a row of pins. Put a small amount of solder on the tip if the iron, and run it down the row to melt oxidized solder off the surface. Then use the solder wick to remove the solder. Before I was laid off, I routinely worked with 288 pin surface mount parts and had to be very careful about lifting pads on $8,000 boards.

After a hole is clear of solder let it cool for a second or two, then touch the tip of the lead and see if it is free. If it is stuck, let the lead adsorb heat from the iron till it breaks free of the plated through hole. Let it go and see that it doesn't stick again. With a little practice you can do a row ow pins very quickly without damaging the board. A good soldering iron is a must, and for modern ESD sensitive parts you need a grounded soldering iron, along with an ES mat and wrist strap.

If you start doing a lot of through hole work, invest in a vacuum desoldering station.

<< If the soldered components are of the 0.1 or 0.15 inch pitched type I would suggest you apply a solder (spring operated piston) sucker instead of desoldering braid >>

Frank-

I think it is a good idea to have both in your arsenal. I've used a spring-piston sucker, as well as a squeeze-bulb sucker and solder wick, and found that the spring-piston sucker had a rebound that damaged the traces of the PCB.

If you are trying to recover components from a scrap PCB, the spring-piston sucker would be most efficient so it would probably be your best choice. If you do not want to damage the PCB, then perhaps the squeeze-bulb sucker or the solder wick would be better.

I have used Radio Shack's solder wick since I don't have ready access to anything better. It works, but I suspect they don't use as much flux in the braid as they could.

Richard- I suggest you pay close attention to Michael A. Terrell's reply. He described the way the professional repair people did it where I used to work.

36V Zeners are available from www.bgmicro.com. I'm not sure about the
power rating though. You might have to use it with a transistor to
handle the current.

Why didn't you just use a Pace station? It seems to me to be rather
risky to use solder wick on surface mount stuff especially with ESD
issues. We are never allowed to use solder wick at work. That said
some of the boards that we do are in excess of 200,000 dollars and are
irreplaceable. These boards are sometimes 8 levels deep and you have
to repair traces that are in the middle of the board. Paces stations
work really well for removing large smd's quickly. Then all you have
to do is run the vacuum over the pads to clean them up.

These were 17 layer boards that came out of the reflow oven with severe problems. We received a bad batch of paste solder, and it didn't show up, till the boards were built. The old solder had to be cleaned up before they could be removed with the hot air system, and some chips were damaged in reflow. They developed microscopic cracks on the bottom that allowed moisture to creep in between the die and the package. By working under a microscope I could find the damaged parts, clean the leads enough to have them replaced, and go to the next board. Another problem was solder balls trapped under the ICs. A little RMA flux, some 2% silver solder and carefully flooding that edge of the chip melted the stray solder. Then you wicked the edge and resoldered. It takes about five minutes a side to fix a 288 pin package. If you are good at SMD work, you can do a better job than a reflow oven.

There are things you will see on a production floor you will never encounter in the field because you don't get a board till any manufacturing problems are corrected. I also did preliminary testing on prototype boards for engineering, qualified new parts and vendors for purchasing.

I wasn't your average tech. Some people there loved me, others hated me, because I wasn't afraid to walk into the head of engineering to tell him there was a problem, and if they couldn't fix it, my next stop was the president of the company. There were a lot of ECOs and major redesigns that I pushed through. I also removed several well know manufacturers from our approved vendor list, because they refused to correct quality problems. Beckman and Vicor are a couple that come to mind. Beckman SMD pots were made with defective seals, so they sucked water inside when the boards were cleaned after reflow. Vicor had a horrible failure rate on their modular power supplies, and changing the supply required a chassis redesign to hold the new power supply.

I have about 6 metal cabinets, vaguely similar to that which houses
a Heathkit impedance bridge. About 7 inches tall, 7 inches deep
on the bottom, 5 inches on the top, sloped front from the top to a
point 2 inches from the bottom, then straight vertical down to the
bottom. Vent holes on the sides and back, access rectangular hole
in the bottom of the back.

Attempt at ASCII diagram, side view:

```
_____
| \
| \
|_____|
```

Various widths from 7 to about 15 inches.

I don't have a use, and need to get rid of some stuff.
Looks too good to toss, so they're yours for the cost
of postage, from Oradell NJ 07649.

There is also the QIL or Quad-in-line format, where altenate pins are offset into second rows. You would have to find a DIL to QIL adaptor/socket.

I guess it all depends on WHY you need wider pin spacings.

I've never used it for rf projects, but for digital it still works just fine
for prototyping. Assuming you still have a supply of chips that are dips.
thanks, John.

Thanks Allison- some good ideas and areas to research. My intention is to
build what R.L. Drake called a "reciter" to go with my Davco DR-30 RX. The
Davco has on its rear panel, the 455 KHz BFO, VFO and heterodyne oscillator
outputs making this approach attractive.

I have had good luck bending pins out with the socket about .05 inches about
the board. Then trim to fit the pads provided. Some very narrow sockets
you can bend the pins out at the point they would normally seat. Others,
with the tab at a right angle to the body can't be bent at all. To much
chance of breakage!

Elektor Magazine did a 2M FM receiver a few years ago. They have good quality PCBs so most of the job is done. The only problem was that the oscillator was free running and tunable. This might not be stable enough. In this case I would suggest a crystal osc for a single frequency, multiplied up. If you want it programmable, you will have to use a PLL circuit, and things start to get a bit harder. Could you try E Bay for an old FM rig and modify it?

<< Rubbing alcohol can be used to remove the excess when you
are through. >>

Bill & Richard-

Ordinary rubbing alcohol has 70% alcohol and 30% water in it. If you search, some drug stores carry 90% isopropyl rubbing alcohol.

You may also find a product in the automotive stores that uses alcohol to remove water from your gas tank and fuel system. An example I found at Walmart, is "Iso-HEET" water remover that contains isopropyl alcohol as its main ingredient. It works quite well to remove solder flux, and doesn't seem to leave any residue of its own.

Santa put one of these kits in my stocking:
http://www.njqrp.org/dds/index.html

So today I had a relaxing morning building the kit. Everything is going according to the notes; except I don't have any output at
all.

I checked the voltages (12 and 5), current draw (93 mA), temperatures of the chips (warm to touch), and I could see bits going in
from SETFREQ.

I just have an Optascope (max 100 KHz), so I tried loading in a frequency of 10 KHz, but I don't see anything on the output.

Has anyone else built one? What can I check next?

Thanks,

Gavin

I picked a laserprinter according to how well it did toner transfer.
Went to all the local stores and got test sheets from each printer,
took them home and ironed on a 2"x2" piece from each. Also made sure
each had the darkness setting turned up.

There was a wide range, some would not stick and some did OK. The
best of the lot was a Brother laserprinter.

Try it yourself and see which ones work.

73,
Jim

This is the second time I've heard of this problem.
I have noticed an error message when I load SETFREQ reporting that the
program "could not open driverLINX driver" but I have no idea what
that is or whether it really needs it to function as I have not tried
it yet.
If you go to OM3CPH's website there is a PC prog there which does
work. Also on that site is a useful "Wobbulator" program using the
AD9850 and an A/D converter to display frequency response on the PC
monitor

Mike,

I was in Pompei in 2000 and saw the lead pipes that were used to distribute water throughout the town. They even had valves to turn the water on and off, It looked like they made the pipe by rolling a sheet around a dowell and then folding the lead to make a seal. They may have used other methods also that I did not see. It was pretty interesting. We seldom give the antients credit for what they did and think of things like indoor plumbing is something new.

According to the guide, they knew that Lead was a problem back then (Pompei was covered with ash from nearby Mt. Vesuvuis in 79 AD). They were in the process of changing from lead to something else which I cannot remember.

They were poisoning themselves with lead, but it wasn't from the plumbing. The water that was carried to Rome from the aqueducts was extremely hard, and a layer of calcium formed on the interior of the pipes just about immediately after being put in use.

Where they got their lead was from storage containers for wine. They used lead containers for this! I believe they credited the lead with preservative powers. The acidic wine pulled a lot of lead out ot the container and into the gullets of the drinkers.

4576. Were IC's ever etensively employed in AM/FM RX homebrew projects?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-28 14:01:26 UTC
From: Richard <nearlynews_email@ntlworld.com>

Source record: 29943
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Although I have been interested an amateur radio for about 30 years, I've never focused much attention on radios made with ICs.

Lately I have got an interest in FM receivers, and have discovered some FM-related IC's/chipsets. ICs such as LA1177, LA1266, LM7000, (these three being a chipset), and LA1235 etc etc.

But, doing a web search , you cannot find any homebrew AM/FM RX using these IC's.

Why is this? I would have though they would be ideal for the hobbyist to mess around with.

90% is out there, but as said, tough to find. 99% sounds like
something from an industrial supplier.

As a caveat, one of the chains had a sale on rubbing alcohols a little
ways back, and one of them was 90% ethanol (denatured). However, the
other ingredients included methanol, acetone, and a few other things
which would make it useless for cleaning. I went with the 70% IPA,
because the only other ingredient was water.

Happy trails,

Rubbing alchohol contains goodies like lanoline or aloe which leaves a
residue. Most of the time it doen't matter, unless, of course you are
looking for high reliability. My local electronics store carries the
electronics grade of isopropanol.

What is weird about the electronics store is that it no longer carries
semiconductors except for LEDs, diodes and selected transistors. They
dropped the line as they said it was not selling and it had a huge
inventory cost. And this outfit is very busy as it sells to installers.
I think their biggest seller is cat-5 cable followed by the hardware
that goes with it. The repairmen have gone the way of the buggy whip
makers.

Most comsumer electronics have gone to the surface mounted devices and few can work on them. The repair people will usually send off the whole board for a replacement they get for a fixed price. Now each manufactor has their own special IC to do the differant jobs. There is no subistution. About 15 to 20 years ago there were several makers of transistors that had the universal replacements where a few devices could replace thousands of differat types.

For some things I remove flux with a spray can of carburetor cleaner.
It is a mix of Toluene, Acetone and Methanol. I bough a bunch of cans at
a dollar store. There are other automotive cleaners that have more
alcohol in them. I think some brands of disk brake cleaner may be mostly
alcohol. I will have to dig into the stash in my shop to take a look the
next time I can spend some time there.

how to sharpen the mini dike cutters and nipper cutters used in electrical & electronic work?

They're too small to handle with jigs, and the blades don't even open very widely. Yet, their utility is directly proportional to how recently they've been sharpened/honed.

I have tried to do this with swiss files and small pocket sharpening
stones. it really isn't worth the trouble, and they never work as
well as a good new cutter. Yes, I hate to throw them away, too.
But, I have bought some good Xcelite and other cutters that have served
me well for years in light production work. I don't cut drill bits
with them, however.

Hi

It could be that the ICs I'm searching under are not popular with
homebrewers. Or, that articles are in printed publications, (like Practical
Wireless etc) or folks just rely on application notes.

ICs I've mentioned are ones typically found in your average AM/FM radio
perhaps in the '90's.

LA1177: Electronic Tuning-Use FM Front End for CarRadio, Home Stereos.
LA1266: AM/FM Tuner Syatem of Electronic Tuning Type.
LM7000: Direct PLL Frequency Synthesiser for Elexctronic Tuning.

LA1235:FM IF Sysyem Applications.

But, I think if anyone wants to mess with these ICs it's more economical to
get some 90's radio, take it apart and rebuild it, with mods. That a way you
get all the hard-to-get bits, like the display.

So, these could be the reasons I've not found many articles incorporating
the ICs I mentioned.

All prices are in US Funds.

QTY. Part # Unit Price Description
---- --------- ---------- -----------
OPTO.

125 TIL311 $7.00 ea. The TI TIL-311 is a Hexadecimal Dot
Matrix Display with integral TTL driver
electronics to accept, store & display
4-bit binary data, Epoxy package
(Note: This part wholesales at about $16.50 each)

8 TIL311A $7.00 ea. The TI TIL-311A is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Plastic package

10 DIS1417 $7.00 ea. The TI DIS-1417 is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Epoxy package

For a copy of the TIL311 Datasheet see:
http://www-s.ti.com/sc/ds/til311.pdf and it is mirrored at
http://umwnt1.physics.lsa.umich.edu/mttc/images/til311.pdf

275 Green LED $0.10 ea. Rectangular 5mm x 2mm face/lens
$17.50 per bag of 250 ($0.07 each) and

8,250 Red LED $0.10 ea. T1 3/4, 5mm Diameter or 0.2" Diameter
Sharp P/N: GL5PR4 (5mA at 1.9V)
$17.50 per bag of 250 ($0.07 each) and
$100 per box of 2000 ($0.05 each)

106 MAN6440 $0.95 ea. Dual Digit, Green 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 MAN- 6440 ($0.75 ea.)

85 FND6740 $0.95 ea. Dual Digit, Red 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 FND-6740 ($0.75 ea.)

TTL CHIPS, DIP Package

525 7407N $0.18 ea. $4.00 per tube of 25 ($0.16 each)
Hex Non-Inverted Buffer with
Open-Collector outputs

605 74ALS20AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Dual 4-Input Positive NAND Gates

240 74ALS27AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Triple 3-Input Positive NOR Gates

1,325 74LS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

100 74ALS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

RESISTORS

55,000 100 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$15 per box of 5000 or
$100 for 50,000 pieces.

3,400 220 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

3,400 680 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

A pack of 100 resistors is $4 inclusive shipping to anywhere
in the US and Canada

e-mail: jrpart@excite.com

Minimum purchase $4 including postage.

No shipping is included in the above prices. To quote a
total including shipping, I require your full ZIP code or
postal code in addition to a list of what you are interested
in. Please specify the country for international orders
outside of North America. The shipping you will be quoted
is the cost of the postage stamp (plus insurance if requested).

The only part that I will ship for a total of $4 (by regular
mail) to anywhere in the US and Canada is a pack of 100
resistors.

All components are new. All semi-conductors are stored in
anti-static tubes/bags or on anti-static foam if you purchase
less than a tube/bag.

Offers on the lot are welcome. Keep in mind that I am looking
for a price below wholesale, but more than the commercial buyers
of surplus electronic parts are offering.

Do you have a friend that works in a machine shop?...No problem for those guys. I had a friend at one company I worked that was a tool and die man. He could put an awesome edge on them. Some of the finer cutters are pretty expensive and are worth sharpening, if not, I might recommend http://www.mcmaster.com/ . They are a pretty good deal for cutters!

Yes, you CAN find the parts...those that survive after the 20 to 30 year
period from their new introduction until now. The MC3362 is a one-chip
FM receiver package available from Kits and Parts. Just add the dual
IF filters and support passives, perhaps a power audio IC for more
sound, maybe an RF stage for maximum sensitivity. Dieter has a
datasheet available for download on it if you like.

Problem is that few of those old ICs survive. They didn't sell well enough
to support continued production. Hundreds of IC designs have met that
fate, were successful, were produced, were sold. They just didn't sell
enough. A few were sold off to other semi makers (Fairchild got all of
the old National Semi digital line, for example...ON Semi got some of
the old Motorola ICs). About three "independent" semi makers in the
USA exist as second sources for old, obsolete semiconductors,
including specialty ICs. The old RCA Sommerville works and their
mighty CMOS line of both digital (CDxxxx) and analog (CAxxxx) got
partially picked up by Harris when RCA was sold to GE, but then
Harris sold off most of those to others, including Intersil and a few to
Maxim (according to part numbers and description).

What you, me, and many other hobbyists have to face is that the
scene in semiconductor ICs is CHANGING. There exist (and have
existed for at least a decade) "foundry" services to allow designs of
complex ICs that may be the entirety of a new electronic project.
Those won't even appear on the distributor market, just single
purchase lot of 100,000 or so, made, installed, and in a successful
product only to be succeeded by a changed, more competitive
device.

You CAN find out much with the right search words, including old part numbers. Unfortunately, many of those old parts have become "unobtainium" and exist only in archival datasheet records. A few remain: MC3362, a one-chip FM receiver; SA602 and SA612 Gilbert cell RF mixers; MC1350 low-VHF differential amplifier; several LMxxx audio devices from National; MC145151 parallel-load PLL all-in-one; CD4046 phase-freq detector for PLLs; 555 timers. The venerable 741 op-amp has long since been replaced by several general purpose op-amps still produced by several makers. Many CDxxxx CMOS digital devices are still available at very low prices (Jameco) and a few CAxxxx analog CMOS are still there.

Outside of the Heathkits at the last decade of their existance, I doubt you will find much in the way of articles and "plans" for a homebuilt AM/FM receiver. When the already-manufactured article costs less than the collection of parts needed to build one, why bother? :-) If you want to build a special version for yourself, there's a heaping glob of appnotes and datasheets for available components on the web...but then you have to DESIGN something (true homebrew) instead of copying someone else's design.

If you want high-proof isopropyl alcohol, you need "reagent grade"
stuff which is available from chemical supply businesses. Clean
room assembly places buy the stuff in bulk. Some medical supply
places have it, too.

When using isopropyl the next thing needed is cotton swabs...lots
of them (on wooden sticks), another expense item. :-)

This brand did list the ingredients, although denaturing is not an
issue with IPA.

The ethanol had a number of ingredients, but no % breakdown except the
alcohol. Told me what I needed.

Careful. Many brake cleaners include lots of toluene and other
solvents which are extremely unhealthy for skin contact or breathing
fumes.

The ones we use (Xcelite microshears, made in the US) are cheap enough ($5-$6 US in small quantities, probably half that for a production shop) to be considered disposable. Biggest problem is with people that try to cut hard stuff (nick the blades) or stuff that's too large diameter with them (snap the blade off).

You've got a steadier hand and better eye than me, Richard...

Whenever I've tried that I've screwed up the parallelism of the blades and they don't touch completely along their full length.

It's not just piano wire and other hard stuff that takes its toll on the blades. I've got what's now a "spare pair' I've had since a kid with a pretty good "war wound" in 'em from the time I forgot which end was up and cut through a lamp cord while it was still plugged into an outlet. (But, they still work great if I'm careful about where I place the wire. <G>)

They are not so easy to obtain in small quantities. They were aimed at
high-volume consumer product manufacturers.

In the early 1970s, the electronics rags were loaded with IC projects.

The problem is that those ICs haven't been made since the early 1970s.

A tube never changes. I can buy a 6BA6 and buld the same RF amp that was
being built in the 1950s and 60s.

I can substitute a 6AU6 and it will still work.

I can use transistors and do the same thing.

An IC has internal "wiring" that is specific to it alone. If you can't get
that particular IC, you can't build the project.

The "Guru of Advanced Thinking About Advanced Radios" of Rockwell-Collins gave an interesting talk at the Cedar Rapids Central States Conference a few years ago.

One point he made was that (even) Collins had to buy enough chips for their complete expected production run, and eventual spare parts, right at the design-in stage. Otherwise either -

1) The part would be unavailable before the production run was completed, or
2) A part with the same number would be available, but it would be enough different that it would either not work or would degrade performance.

Even the Big Boys have parts problems.

> high-volume consumer product manufacturers.

And that leads to another reason why they aren't used.

They are intended for very specific use, in something that will be
built in large quantities with the same design.

But what works for an AM/FM broadcast radio may not be best for some other
use.

I remember when RCA came out with the CA3088 AM receiver on an IC back
in 1971. QST ran an article about it, hinting at big things, yet also
pointint out deficiences. It was intended for a 455KHz IF, so you'd
be stuck with image problems as you started using the IC in the shortwave
range. I think there might have been limitations on the IF strip so
you couldn't run it at a higher frequency. The mixer was a single
transistor, and if I'm remembering, it was used as the local oscillator
also. Maybe okay in a generic broadcast receiver, but not great for
higher frequencies or where better performance was desired. The detector
was built in, and of course, it was AM only. There was no easy way to
bypass that detector, at a time when few hams would want to build an
AM only receiver.

In trying to fit a very specific application, it was lousy for more
general use.

Since then, there have been plenty of AM and AM/FM radios in an IC.
Some have worked better than others for other uses (who can forget
Ralph Burhan describing Loran C receivers using them?), mainly because
they were less integrated, or at least had pinouts in the right places.

Less grandiose ICs work better. The Motorola FM IF strips were at
first just the IF strip, and since they were intended for narrow band
FM, they were better suited for use in amateur applications. Even the
later variants, that added the front end, had the advantage that the
input and outputs were available off-IC so one could fiddle with things
where needed.

And then when you get to the point where an IC is simply taking care of
one stage, such as a mixer, or an IF amplifier, there is infinitely
more use of them in various designs. Of course, they are less useful
to mass marketers, because they take up more space and give more performance
than needed for AM/FM broadcast, so there is a limited market for them.

Realistically, now-a-days, IC's are mostly "systems-on-a-chip", and
are usually custom-designed for a specific application; jelly-bean
analog chips (except perhaps OpAmps and linear voltage regulators) are
gradually fading from the scene.

If you're handy with tools and have some ingenuity, you could use a
Dremel with the thin cutoff wheel. BUT you would have to clamp the
Dremel and then secure the dikes at the proper angle so you could
slide the blade along the cutoff wheel, being sure the edge was in the
plane of the wheel. The grinding would be done with the face of the
wheel. There ought to be enough room to let the wheel in.
Anything less than that and your dikes will be ruined due to lack of
parallelism.

For those who are trying to learn the Morse code, there is no better way to learn it than by the Koch method.

In my opinion there is no better software available using the Koch method than the marvelous program from Ray Goff, G4FON of the UK.

This program begins with the practice of just two letters..when they are mastered another letter is added to the mix...when they are mastered, then another letter added, etc. And YOU'RE the one adding additional letters at your own pace.

It's easy, and it's the fastest way I know of to learn the code, and the software is free.

Is there anyone who would care to admit that they cannot learn 2 letters of the code? If you can do two letters, you can learn the entire code.

The G4FON Koch CW Trainer version 6 is available for download at:

www.qsl.net/g4fon

Most denatured alcohol is denatured with methyl alcohol. The water is just there to dilute it.

But the denaturing can be done with several substances.

http://laws.justice.gc.ca/en/E-14/C.R.C.-c.568/98295.html

has some regulations for denatured alcohol. It's for Canada, but I'm sure it will apply to most places. It is fairly far down the page.

Okay, from what folks have said, I gather that as time has moved on, ICs relevant to construction of AM/FM radios have tended, more and more, not to appeal to homebrewers because their specs are seen as not being that good, and they have lost much of their flexibility/applicability - due to current design/production/marketing trends.

If you buy a top quality cutter, and keep a cheaper pair for piano wire the good pair will last several years of use, and occasionally you will have to throw away the cheaper cutter.
Compound leaver types generally have blades which are less sharp and withstand abuse better than normal cutters so use this type for the piano wire.

It's not normally worth the effort to do a proper job of re-sharpening, cheaper to buy a new pair if you value time.

Jonathan

Barnes's theorem; for every foolproof device
there is a fool greater than the proof.

That is what I expected, and would have been fine with. But this
particular one has acetone, and several other things. Since I didn't
buy it, I can't read off the other ones.

The regs say that it must be denatured to avoid certain taxes and
sales regs, but I agree that there are multiple ways to do it.

Good point. Anyone else remember the TV miniseries Twin Peaks, where the opening sequence showed an automated sawmill-blade-sharpening machine?

A true story: I bought my first pair of cutters when I was working summers as an apprentice electrician. Sometime during the second summer, I cut a live cable, which burned a notch in the blades just perfect for stripping #14 wire.

A couple of years back, I changed jobs, so I was retrieving my tools from the R&D lab. I saw a pair of notched-blade cutters just like I remembered. After a brief discussion with one of the lab techs, who said they were his and had a story similar to mine. I thought that was too much of a coincidence, so I stuck them in my toolbox.

Last month, I was cleaning out my garage and found two pairs of notched-blade cutters.

I sharpen for a living.
My advice is to do them by hand with a diamond file such as an ez-lap
Grinding takes off too much material too quickly and you never get
them to meet just right.

How many brands of desoldering braid are there, and how distinctive
are they from each other?

I have seen at least a half dozen brands. They seem to have different
flux formulations because some work a lot better than others. That is
why I switched to buying bulk ground braid and liquid flux. (Kester 197)

I have a bunch of oddball crystals that I want to test. I know I can just build up a generic oscillator to find the resonant frequency, but out of curiousity I would like to know the quality of the things, too.

Anyone know of any neat ideas for measuring the Q of a crystal?

I would welcome any and all suggestions,

I use it to clean flux off soldered metal shields, or when I restuff
oil filled bathtub capacitors. I'm aware of the damage to plastics. I
worked in electronics manufacturing myself. In some ways I miss the
circuit board washing machine, and just handing a board to the woman in
the cleaning room for hand cleaning after I had repaired it.

Yes, I have seen it that way, and we used enough to need the 55 gallon
drums.

Goes to show that reading labels is important for all sorts of things.

At another time, I was at a place which had a process which required
the pure 190 proof ethanol. As this was drinkable, it had an ATF tax
stamp just like you would see on a bottle of liquor.

Since the tax is proportional to the alcohol content, the tax was more
than the alcohol itself.

If you have access to old QSTs, you should be able to find articles about measuring crystal parameters. Look especially for things by Wes Hayward, W7ZOI. There's a fairly simple crystal-tester you can build to measure enough parameters to extract equivalent L, Cs, Cp and R, I believe. I 'spose someone will pop in with a more specific reference for you.

Cheers,
Tom

Hi,

To calculate Q at series resonance, you will need to ascertain both the effective series resistance and one of the series reactances (XL or XC). In his Jan/Feb 2002 article "Quartz Crystal Parameter Measurement", Jack Hardcastle, G3JIR uses a simple test rig and a mathematical/graphical method to determine both the resistance and effective series capacitance.

There is an obvious error in the circuit to look out for though, where an extra series crystal (Y2) was inadvertently added by the draughtsman.

Cheers - Joe

I have had very good results by grinding across the flat closed face of the cutters.
If you look at the construction of the closed jaws, you'll probably see that they form a relatively flat face on the outside, with a vee-shaped profile on the inside. Also, if you hold the cutters up to a light with the jaws closed and the flat face towards you, you can easily see any places where the jaws are 'dinged'.
Now take the cutters over to a grinder or belt sander and, keeping the jaws closed, grind the flat face away uniformly. As you remove face material, you'll see that the jaws take on a very sharp new edge and there will be less light leakage through the closed jaws. Make sure you don't use a grinding wheel or sanding belt that is too coarse for this operation. For the final step, lap the newly ground closed face with a finer abrasive.
While at the grinder, I also like to form a nice sharp peak at the tip of the jaws so I can get into small places and cut fine things (like one leg of an IC).

You can get a uniform, razor-sharp cutting edge with this technique. It's good for a couple of re-sharpenings, then you should discard them.

Grinding won't take off too much unless you do just that! I watched a tool
and die man sharpen a pair of flush cut dikes to like new on a special
grinder used in that industry.
The big catch is..."do you have a friend in the machining biz"!

I agree 100%. I used to work in the tool crib for a company that made cable assemblies and wiring harnesses. We needed sharp dikes for cutting small wires and deflashing overmolded connectors. I used a diamond file (DMT Duofold), or a bit of fine sandpaper held against a 6" steel rule. You need to be careful not to round over the tips of the blades.

Good quality small dikes are expensive. I think we paid about $35 for Lindstroms, and around $50 for Swanstrom. These cutters can last for several years of heavy use if they're taken care of and not abused. Cutting hard wire or dropping them point first on a hard concrete floor can ruin them instantly.

Swanstrom offers a reconditioning service for dikes, but they have a minimum order of $75. <http://www.swanstromtools.com/recon.htm>

I selling some old toys so I can get new one's.

Kenwood TL-922A Amp.
Will do 160-10 meters but 10 meter option not installed, 1.5KW, (2) 3-500Z
Very nice condition with a few scatches, will send pictures on request.
$950.00 O.B.O plus shipping.

ICOM IC-2720H
2 Meter / 440 Mhz daul band mobile, lots of features and in new condition.
Radio is 6 months old. $275.00 O.B.O plus shipping.

Yeasu FT90R
The radio is in new condition but I lost the manual and mobile bracket.
Should be able to download the manual from Yeasu's site. $175.00 O.B.O plus
shipping.

Will send pictures on request.
Please contact me at.

> notched-blade cutters.

reminds me back in 1993 we just bought a new 93 taurus, silver/blue... no tags on car yet... went to check on something at college with the whole family... it was hot as hell out there... going back to the car the wife say, "for christ sakes dont just stand there, open it up and start up the air." I look inside and see a box of tissues on the seat... ask the wife did she leave them there.. she says no.. i said then this is not our car(an exact copy of it though).. ours was on the next row... back in 1956 as i kid i remeber a story a friend told me: his uncle had just bought a 1956 ford, victoria, convertible, black and yellow(with a black rag top)... pretty nice looking car back then.. the uncle and his wife go the the supermaket, park the car in the lot(big lot) and buy the groceries and come out and open up the car and then open the trunk... the uncle ask the wife if she put all these clothes in the trunk... she says NO.. they then figure it is not their car..... they look all over and cannot find their car anywhere... they call the police... the police then check out the car and find out where it was sold and the vin. number... they contact the dealership and find out who bought it.. an old man who lived in the neighborhood... they drove over to his house and find that he drove off in his uncle's car and put it into his garage..... so with a pair of pliers i guess it can happen....

4630. Toluene (was: Who makes the best solder braid?)

======================
Indeed especially the toluene (a benzol derivative) is particularly nasty .
Do NOT bring in contact with skin or inhale. It can cause cancer.

Many moons ago some benzol (chemical formula C6H6) was added to car petrol
to increase the octane rating , but because of the above problems an
alternative was added to achieve the same. Also certain paints (for example
those for concrete workshop floors) contained toluene (an excellent
solvent) but these are now banned ,at least in the EU.

As co-ListOwner/co-Moderator of the RADIOSHACKDX394 and DX-394C Yahoo groups, I think I have a small obligation and privilege as 2003 draws to a close to look back over the past year in the life of our subject, the remarkable Radio Shack/Realistic DX-394 communications receiver plus the activity in our groups and share some observations with you. This has indeed been a remarkable year for both - the number of messages and growth in membership perhaps being the easiest indicators.

Over the nearly three years since jimtown54 founded RADIOSHACKDX394 it has grown to some 550 members, one of the largest product-specific communications receiver groups in Yahoo, second perhaps only to the DX398 group. The message archive has mushroomed from a mere 88 messages added in 2001, an explosion of 546 more in 2002, to an amazing 1450 new messages in 2003. This signifies a growing knowledge of our DX-394 community and keen interest in the possibilities for improving this economical, feature-rich radio. Most members are from the US and Canada, there's a significant number from the UK and small numbers from almost every continent.

Early this year, I was prompted to consolidate all the known modifications into a master list or index so that people would not have to search in the thousands of messages and scattered pages on the Internet to discover the proverbial needle. Through the year, this index has grown to include 62 mods - by far, more than for any other radio. For those willing to experiment with and learn a little radio-electronics, there can be few more intriguing and rewarding platforms than the DX-394 as it combines both digital control and conventional analog RF electronics in a box that is larger and more spacious than most radios in its price range. It is relatively easy to work on, if you have good eyes and a steady hand!

Interest in the digital control possibilities led to the formation of the DX-394C group last winter - now numbering 91 members and 89 messages. Few have undertaken the challenge of converting the DX-394 to computer control but the Files section is a rich trove of information to help the daring ones embark. The group has been quiet since April - I hope to see more activity through the long winter nights and to resume my own PIC-based project (or re-launch it on another platform).

Later in the year, John (KB9KQN) launched the DX394L group for those disinterested in modifications and wanting a community of fellow DX-394 users with whom they could exchange general listening tips and interesting frequencies.

John and Howard (derny_99) agreed to take on co-Moderator responsibilities for RADIOSHACKDX394 - new membership requests are now processed by one of us

within hours of the application. Spam and off-topic postings have been pretty well controlled. Recently, we escalated the security and now require Moderator approval for initial postings from new members.

Trade in the DX-394 on eBay continues at a steady pace since I started tracking sales from Oct 24. Fifty DX-394's have been sold since then, an average of over 5 per week. Average selling price was US$159 out of a range from $105.50 to $265. The higher prices being commanded for well-modified radios.

So 2003 has been a banner year for the DX-394. Let's hope it continues in 2004. I wish you good health and prosperity in the coming year along with great listening and learning with your DX-394(s).

73, Tom VE3MEO

Do you want to broadcast a large number of different signals simultaneously
from the same transmitter, or many copies of the same signal?

Both should be pretty straightforward to do... if you want to broadcast
many copies of the same signal, you could just replace the LO with
a circuit that generates a number of carriers, superimposed. Each
frequency component in the LO will produce a corresponding copy of the
audio signal in the RF or IF output.

I don't know if it's possible to broadcast a single audio signal spread
over a wide band (instead of having one copy at each standard AM station
frequency, as above). My intuition says it should be possible to
amplitude-modulate some wideband noise, and any AM receiver with an
envelope detector would recover the signal. But mathematically, I'm not
so sure --- where would the sidebands go, how would the receiver
distinguish them from the overlapping "carrier"? Or could this be
thought of as a sort of self-despreading spread spectrum signal?
Perhaps I should just go to bed ...

Joe (#7 in the responses) has the right idea. But the best tool for sharpening small dikes is a one inch belt sander, used where the belt is not backed up. It is pliable enough to follow the contour of the cutters. Try to use a grinder and you will have to be six times as careful. The magic trick is to grind where the cutters touch, and not grind where they don't touch. Eventually they will touch everywhere. Cut a piece of cardboard ever once in a while during the grinding process to keep the feathered edge from faking you out. The cutters will come out as flush cut cutters. A little touch-up with a stone to get a more severe angle at the edge will make them a little tougher. I usually don't bother.

I have sharpened cutters like this for probably 25 years. When I throw away a pair of cutters, the metal on the handle side of the hinge pin is probably hitting before the blades close. I have filed away the handle side a couple of times when I liked the cutters and wanted to sharpen them one-more-time. The mark of a good pair of dikes is whether it will cut a hair right at the tip.

4636. CW software decoder algorithm?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-30 03:49:39 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <3ff0f678$0$1752$5a62ac22@freenews.iinet.net.au>
Source record: 29852

Dear all

I am looking for ideas for a software CW decoder with ASCII output.
There are a number of programs published - what algorithms do these use in general?
I presume the software would have to have some sort of PLL to select and filter a signal
and then an adaptive algorithm to allow for sending operator error in keying, noise and variations in keying speed. I am looking for a solution which trades off accuracy for minimum codespace and speed. If necessary, some of the work could be done in hardware - eg I could limit and square up the audio waveform and present it the processor as digital level transitions, so AGC would not be an issue.
Any ideas?

Thanks in advance

Richard

There are two steps that you have complete: make a digital signal out
of the received analog output - and decode it.

Have a look at:

Wolfgang
Thanks for your reply
I am not very sophisticated mathematically and I have not studied communication theory. Your article is most helpful. However it looks as though it might be somewhat hard to implement in a small/slow codespace such as a microcontroller. (It may well be impossible to do this job in such a device.)
Still I thought I would try.
Off the top of my head I thought I would start with a hard limited audio signal, with transitions at digital hi/low level, rather than a sampled signal. This would obviously limit the signal to noise ratio, but I was not planning to use this for weak signal work. The clock/demodulation algorithm would then deal with the timing between transitions of the signal, rather than a spectral analysis. This would be relatively simple to implement with a timer to count the interval between transitions. The controller could track carrier freq with a Freq Locked Loop algorithm, over a limted range.(say 600-900 Hz) If there are no transitions or randomly timed transitions (noise), then the controller assumes a space Similarly, the controller tracks sending speed by timing the length of dots and dashes, and adjusting the algorithm to track this. This length could be initially acquired by timing an initial series of dots/dashes. The length would presumably fall into two groups, with the shorter length being dots. The average of these shorter "on" periods would be the bit rate. The controller could keep a moving average of the signal, discarding any "on" periods that are longer than say 2.0 times the current average. Finally, I would use the bit rate to time gaps >(say) 2.5 times the bit rate to separate characters and decode them with a simple lookup table.
No doubt there are lots of problems with this approach!
I would be interetsed in your comments

Richard

I've come to the same conclusion. A good pair of mini-dikes is worth the investment, so much so that I asked my wife to get me a Xcelta pair of flush cutters for Christmas -- they were about $70. I've pitched the Xcelite ones. After a year or so they are just shot.

Would also be interested, but have not experimented in this field
since I used the Apple II computer. Good decoding was a problem, but
also too often simple detectors were described. I did some experiments
with slide-back detector which was originally constructed for two-tone
RTTY (850Hz shift) and as such a good choice for single signal, but I
couldn't see much difference from the ATC network used for RTTY

Also had some good experience with MC1496, S042P similar detectors
instead of using envelope detectors

I've been to about 5 different radio related groups this morning lurking for information about a problem I have in a similar field to this duckman guy, and (1) his request has been -- identically worded, if not mistaken -- in each of the groups I've read, a couple related to pirate radio, a couple related to professional broadcast radio, and a couple related to ham radio. What gives?

Anywhoo, I've got a similar question I post shortly.

I know someone who has a desire for a piece of equipment that does the same thing, but his reasoning is for people who blast their radios while going down the street. It would be merely for shutting them up -- after all, the person blaring the radio is usually the only one who wants to hear it.

Many years back, I built a TTL deocder from a QST article- by Petway??
Anyway he used a number of storage registers- one for average dot length,

one for average character spece length and one for average word space length. After initialization, a clock would run at the receipt of each element. The count was then compared to previous average- if the clock count was larger, the average was incremented by 1; shorter, it was decremented by 1.
The machine did a surprisingly good job on hand sent Morse. Although the hardware technology is antiquated by today's standards, the algorithm was elegant and easily understood. I would estimate this article (2 or 3 parter) appeared in QST from the early 70's.

> -vs-

Let's see if I can describe a method based on W7ZOI's efforts, with some updates by K8IQY. By the way, the W7ZOI techniques from QST were added as appendixes into one of Doug Demaw's ARRL books. Demaw integrated Hayward's various test jigs into one crystal tester. You can get a board from Far Circuits.

You put the crystal in a specific (typically 50 ohm) environment by putting 50 ohm attenuators between generator and crystal and between crystal and detector. The detector might be a diode detector plus voltmeter or an oscilloscope. You'll also have another 50 ohm 3 dB pad in series that can be switched in and out.

1. With the pad switched IN, adjust frequency until the peak output is read (resonance). Note the center frequency and meter indication.

2. Switch the pad OUT and find the frequencies above and below the center frequency that give the same indication. These are the + and ï¿½ 3 dB frequencies and the difference between them is the bandwidth.

Now you can calculate Q by dividing the center frequency by the bandwidth. Pretty low isn't it? This is a loaded Q, not the crystal's Q. The total resistance in the circuit is 50 ohms source plus 50 ohms load plus the crystal's yet unknown Rs.

3. Tune back to the center frequency where the output is at its peak. Unplug the crystal and substitute a pot of maybe 0 to 25 ohms range. (I actually just substitute fixed resistors since I don't have a decent pot like this.) When you find a value that gives the same meter indication as the crystal did, that is the value of Rs. (This is because we are at series resonance, so Xc and XL have cancelled.)

Alright. Another formula for loaded Q is XL / R. R in this case is 100 ohms plus the Rs you just measured. And XL is 2*PI*Fc*L, where Fc is the center frequency you measured earlier. You already have the loaded Q from step 2, so you are down to one unknown. Just solve for XL and/or L, which is the equivalent inductance of the crystal. In like manner, you can find the series C, since Xc = XL.

And finally, the Q you wanted (the crystal's Q) is XL / Rs.

Now you know about everything about the crystal and can get one of your Hayward or Demaw books and start designing some filters. Hayward has nice software for this in both Introduction to RF Design and Experimental Methods in RF Design, both from ARRL. If you want to include holder (parallel) C in your modeling, 5 pF is a good estimate.

Jim Kortge, K8IQY puts his crystal in a 12.5 ohm environment by using 4:1 (impedance) bifilar transformers into and out of the crystals (50 ohm attenuators are still used though, to assure known generator and load resistances). This has the advantage of making the resistance measurement easier, but it makes the loaded bandwidth smaller, so you need a good stable generator that you can read to the Hz. Those little DDS units are nice. Be sure to use filtering if necessary for signal purity. Jim designed a nice little VXO (variable crystal oscillator) that uses one of the crystals from the set you are measuring in the oscillator circuit. See it on NJQRP's page:

http://www.njqrp.org/pvxo/index.html

I followed Jim's lead but used resistive 50 to 12.5 ohm matching pads instead of transformers. That way I got rid of any reactive effects (which are minimal) of the transformers, but required a lot more driving power due to the loss in the matching pads.

OK, that was probably more than you wanted to know. Hope I remembered this stuff right.

Hello group

Forgive me for not lurking a bit longer here, but there's plenty of interesting topic here so I'm going to be reading for a while yet....

I have recently built a small FM-Broadcast-band transmitter. I did this a year ago when I was spending a lot of time in the hangar working on my car. I got tired of all the crap my local radio stations are playing, and I simply don't have any locals that play anything decent.

So, I have my own collection of music that I wanted to pipe out to the hangar.

The first option was MP3's and playing them into the hangar's radio's line input via my laptop. Well, this got real old, real quick. I decided the better option was to take my desktop and add a line output to a small transmitter.

I built the transmitter (I'll get the URLs for the schematics if anyone wants them - they're very basic, and I very slightly modified them) on a Radio Smack breadboard I have, and it worked great. I even had it feeding a 10-foot length of 75-ohm TV coax into a pair of 30-guage antenna leads at the other end - I forget the actual length, but I think that each lead (dipole) is about 4.75 feet. I don't have my scratch papers with me, so I forget the numbers I used, but I think I was going for a half or 5/8 wavelength at center band (88.1 - 107.9 : 95.5???)

ON THE BREADBOARD, the thing worked beautifully. I live on an airpark with a 2600-foot runway, and we live in the middle. I drove in my car with a handheld FM receiver and I picked up the signal - barely - at the end of the runway, so I have about a 1300-foot radius of signal. That was then.

I decided I liked it enough to solder it together. Using a different style of PCboard (e.g., it didn't match the breadboard) it no longer worked. Same components, electronically the same positions. Triple checked. Twice. Then rebuilt twice, and checked again. Didn't work.

I decided this year to try again, starting from scratch, on the breadboard. Got it working again, if not as well, so I soldered again - this time to a matching PC board pattern. This time it works, but very very limited range.

I have tried various coils. Most homemade, one out of an old 49 MHz Walkie Talkie, and some commercial from a Radio Splat variety pack. I'm also using a ~ 20 to 40 pF variable capacitor from an old AM/FM handheld receiver.

When I use a very short (e.g., < 4 inches) antenna, it transmits, but only to the bathroom (about 10 feet away). If I use longer wire, it has to be coiled up, and is still very short range. I was using an external dipole before and got great range (considering) from it, and I want to continue using that.

I normally would think that one lead of the dipole goes to ANT OUT, and the other to chassis ground (which for a 9-v battery-operated device, I would expect to be the - leg). That kills it. If I have only the one lead of the antenna hooked up, I can get some signal, but not very good range (only slightly better than with 4" antenna). I discovered by accident (using a bare wire coil and having a loose shield of a piece of coax accidentally touching it) that by grounding the shield of the coax to POSITIVE 9v that I can tune it. But, that was still not a very good tuning. Range was okay, but still limited to about 20 feet.

I'm not too worried about it, except that I *KNOW* I am capable of a 1300-foot range with this thing, so I'd like to get at least a healthy proportion of that back (I might use this as a community radio that would have a total of about 60 homes in its range).

I find that the best result I've had over the past two days is with a bare wire coil, about two turns, on about a 3/16 " diameter wind. Aircore. Spacing about 1/16th to 1/8th of an inch. Unfortunately, I was unable to test my range when the "accident" happened, and also, I have not been able - with like components - to duplicate the "accident" exactly.

The transmitter itself works beautifully as far as tuning and stability and clarity and volume, if there is no antenna. Any antenna at all, and it won't tune.

I have looked on the web for information, but I've found nothing that helps me... only websites selling commercial radios, kits, etc. that I can't afford, being a poor college student. I've looked in the Radio Amatuer's Handbook for 1993, the latest edition we have, but it didn't help me - a bit too technical, and I'm a hands-on learner (also didn't help that the handbook uses parts I don't have and can't buy from a local Radio Slack store shelf). I also checked out the Antenna book from same year, it was about as useful as the R.A.H.

I know that without the schematics (sorry, I don't have time to get them now, but I will later if needed), and without seeing the device, it would be hard to tell me what's going wrong. I will take any advice into consideration though.

Many TIA and 73 de KE4EDD

Hello there,

I'm hoping some of you telegraph key and sounder collectors/operators will have an answer for me.

I've got a 1000 ohm sounder here that I'd like to operate. Is/was there as standard/defined voltage or current used by telegraph services for the various mechanical telegraph sounders, based on their coil resistance?

Thanks for your reply answers.

If you just want to jam, build a 10.7 MHz transmitter and turn it on when
desired. Most cheap radios don't have good IF rejection and the signal
will capture the normally weak incoming signal from the broadcast.
However, the whole thing is illegal no matter what the method.

Source record: 29876

Disclaimer: I've never decoded morse in my life, so most of what I write is educated guessing.

For my master's thesis I built a receiver that demodulated 400 baud MSK. The RF chain delivered a signal centered around 2kHz to a 68HC11 which sampled at 6400Hz and demodulated the data entirely in software -- and it only had 2k bytes of code space. Granted, it was all in assembly, and it used 94% of the available processor time to do it, but it did work. In spite of having some really ugly compromises in the signal processing (the sampling rate was really too low, and the only "multiply" was to add, not add, or subtract from an accumulator) the receiver had performance within a dB of the theoretical optimum. I think with something modern like an AVR or a PIC a 16-baud OOK signal should be possible (fun, too).

OK, so you still have the problem with the math.

Consider using not one, but two comparators to square up your signal, so a "non-signal" rarely gets above the threshold. You're back to needing AGC (at least to set the comparator), but you can close the loop in your software by looking at the comparator outputs for the right signatures (too much output = too low threshold, too little output = too high threshold), and set the threshold from the uP. With a good signal to noise ratio this should have a nice broad center to it that'll be easy to find. With a good narrow CW filter your signal to noise ratio will get better...

Once your threshold is set you can integrate the "buzz" from the comparators to see if you're receiving a carrier. You should probably integrate for some period of time (the length of the fastest code you want to receive would be good, it'd give you a sorta-kinda-matched filter) and take the presense of signal 1/2 of the time to indicate the transmitter is "on".

I like the idea of using the dibits to form a PLL, but for receiving bad code at an unknown rate you'd probably be better off making a little histogram of the on and off times of the code. You should be able to see two peaks in the histogram for "on" corresponding to dot and dash, and three for "off" corresponding to intra-letter, inter-letter and inter-word spacing. At this point you can start looking for dashes, dots, and spaces (maybe going back over your data to catch the beginning of the message, if you have enough RAM) and decoding words. You could also estimate the speed of the code that you're receiving and feed it back to your KSMF (that's kinda-sorta-matched filter, of course) for better noise figure.

Once you have your stream of dashes, dots, inter-charater and inter-word spaces you can separate the charaters, look them up in a table and just reject anything that doesn't seem to fit. I suspect that your performance would be pretty good at this point, and if not the theoretical ne-plus-ultra

of decoders it would be better at receiving the lousy senders than
Wofgang's.

I thought you guys would like to hear about my current project:

40 meter double sideband transmitter. Solid State. To be used with my
Drake 2-B receiver. I wanted something that would allow me to contact
UK hams. My antenna will be low to the ground and NVIS should work fine.

I have kind of unusual VFO: Crystal controlled 10.1 Mhz oscillator mixing
with a 3.0-3.1 Mhz VFO. 40673 mixer. Produces 7-7.1 Mhz signal (European
40 meter ham band). I have two LC filters after the mixer to knock down
the 10.1 and 3 Mhz signals. I plan on letting the 3 Mhz VFO run all the time
(in both transmit and receive modes) -- I'll switch the 10.1 Mhz crystal
oscillator off when in receive mode.

Balanced Modulator is an NE602 using the circuit from the K2. This produces
a very nice deep null in the carrier.

I'm using a D-104 with the transistor amp in the base, so there was no need
for an audio amp in the rig -- D-104 goes directly into the NE-602.

RF amp is from a Doug DeMaw article in the Feb 1997 issue of CQ. Looks like
I'll be getting at least a few watts out.

I did the initial tests this morning -- all systems go. I should have it on
the air this weekend. It will have a real wooden breadboard for the base, and
an aluminium "kick panel" (for a door) for the cabinet.

I'll keep you all posted on progress.

> device.)

In the August '98 QST, IK3OIL published an article on a CW decoder based on a PIC16F84, which may well be, by today's standards, the most limited microcontroller in use by hobbyists. (Well, I suppose you could tie one hand behind your back by adding a Basic compiler on top of it or something like that!) That particular device, while far from perfect, works a lot better than the various PC based programs that I've tried.

Last I looked, he still had most of the information on his web site. I know others have done work to improve on his program, but I don't know of any of that work that has been published. One nasty feature is that a long series of dahs can greatly confuse his algorithm and it can take a while to recover from that. Were you to implement his algorithm in a '628 or something like that, or even to simply replace the rather lengthy code he has around displaying the speed with a little more work on the algorithm, I'm sure it could be improved.

He did use an external decoder to recognize the CW signal, a 567 or something of that ilk. Some folks have worked on that end, too. It seems like there should be a better approach, but I haven't seen anything dramatically better.

..

I said I'd get the schematics, here they are:

http://www.reconnsworld.com/transmit/fm_trasm.gif

Actually, mine were printed out from that page, but it seems the guy has added a whole bunch more since I was there. I printed this out a year ago (12/13/2002) and he added some stuff in mid-2003... Got a 3W transmitter, a 15-18W transmitter, an IC-based stereo transmitter, a 48 MHz beacon transmitter... neat stuff indeed.

Anyway, I've gotten a couple of ideas from looking at the more complicated designs, and I'm going to try a coupld of things and see what works and what doesn't. I'm still very interested in any thoughts the groups has to offer about why mine works as marginally as it does...

TIA and 73

4663. Re: Transmitter tuning, antenna, etc

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-12-31 15:42:14 UTC
From: Joe McElvenney <ximac@btinternet.com>
Message-ID: <VA.0000000c.003e9637@btinternet.com>
Source record: 29880

Hi,

Further to my e-mail, having seen the schematic now, it is probably the antenna which is screwing things up.

Firstly, take the antenna off the collector of the oscillator and either link-couple it (a couple of turns with one end grounded) or tap it down the tank coil till the oscillator starts reliably. You are not looking for an exact match here but a way of coupling energy more efficiently into the antenna without the oscillator thinking that it's his mother.

Secondly, the base biassing you have on the oscillator is too dependent on individual transistor parameters. I suggest that you connect the base to ground through another 10K and then adjust the emitter resistor until you have 5 to 10 mA flowing through it. You can tell when you have it about right by measuring the voltage across it. Touching the circuit near the coil with your finger should also show some variation in voltage if the circuit is oscillating.

Finally, you appear to be relying on the battery for an RF return circuit which is not good. Try placing a capacitor of about 0.01uF between the supply and ground, close in to the oscillator.

Cheers - Joe

Okay, I've not had the experience with this, but my father has. I normally would ask him for help, but lately, he has been irritated when I have asked, I suppose because he thinks I already know a lot of these ideas. Anyway, having used your reply, I was able to get him to explain what you meant.

In my discussion with him, he mentioned that because of the simplicity of the radio, I would have what amounts to line loss by link-coupling the antenna. He suggested the tapping bit. After explaining that to me, I recall now having seen schematics that used that technique. I think that's what I'll try.

> You are not looking for an exact match here but a way of coupling

If I get the image you're trying to send, I must say that's one effective way of getting your point across ;-)

Sounds easy enough. I assume you mean the base of Q2?

> Finally, you appear to be relying on the battery for an

And this seems to be standard practice, the capacitor. I've seen reference to that on just about every circuit dealing with oscillators (I have a small collection of "Engineer's Mini Notebooks" from Radio Snap, along with a book from an old electronics lab kit I got about 14 years ago. Shouldn't be a problem to implement.

> Cheers - Joe

Thanks for the help, Joe - I'll let you know how it goes when I get the chance. Right now my father's needing my help loading a trailer with some carpet and then we're off to our old house to see if the carpet can fit in anywhere. After that I should have a few hours to tinker, I'll try this then.

Cheers to you, and 73 de KE4EDD

Hi, Nick,

No, not more than I wanted to know at all. I'm quite happy to have this
level
of info.

Thanks for the detailed reply -- gives me something to mull over during the
holidays.

Down East Microwave (www.downeastmicrowave.com) has a limited
selection of diodes. You might try a post to WA1MBA's microwave email
reflector (see wa1mba.org for details).

I tried Microwave Components but their number has been disconnected.

Help!
I need a manual for a Leader LAG-26 audio generator. the Lodestar AG2601a
may be the same unit

AAAAAAAAAARRRRRRRRRRGHHHHHHHHHH

Trying to get the homebrew 6L6 modulator working I accidentally toasted the
input to my leader LAG-26 audio generator with 500VDC into the audio out.
Several resistors, possibly some transistors went south. Anyone have a
source for the manual? I have not been able to locate one on the web.....

Thanks and 73

I'm looking for ideas for a stand alone timer to turn on and off a remote shortwave or BCB receiver and tape recorder. No AC mains available. Switching requirements no more than about 5 amps.

Haven't had much luck scouring the web.

Ideas?

John WB9UAI

4670. FS: Lots of 500: 50V 22uF Electrolytic Capacitors :: $ 27 SHIPPED
